ABSTRACT

Adenosine triphosphate (ATP)-sensitive P2X₇ receptors are localized on cells of immunological origin including glial cells in the CNS. Activation of P2X₇ receptors leads to rapid changes in intracellular calcium concentrations, release of the pro-inflammatory cytokine interleukin-1 β (IL-1 β), and following prolonged agonist exposure, cytolytic plasma membrane pore formation. P2X₇ knockout mice show reduced inflammation as well as decreased nociceptive sensitivity following peripheral nerve injury. A-740003 is a novel competitive antagonist of P2X₇ receptors (IC₅₀ values = 40 nM for human and 18 nM for rat) as measured by agonist-stimulated changes in intracellular calcium concentrations. A-740003 showed weak or no activity (IC₅₀ > 10 μ M) at other P2 receptors and an array of other neurotransmitter and peptide receptors, ion channels, reuptake sites, and enzymes. A-740003 potently blocked agonist-evoked IL-1 β release (IC₅₀ = 40 nM) and pore formation (IC₅₀ = 60 nM) in differentiated human THP-1 cells. Systemic administration of A-740003 produced dose-dependent antinociception in a spinal nerve ligation model (ED₅₀ = 19 mg/kg, i.p.) in the rat. A-740003 also attenuated tactile allodynia in two other models of neuropathic pain, chronic constriction injury of the sciatic nerve and vincristine-induced neuropathy. In addition, A-740003 effectively reduced thermal hyperalgesia observed following intraplantar administration of carrageenan or complete Freund's adjuvant (ED₅₀ = 38-54 mg/kg, i.p.). A-740003 was ineffective in attenuating acute thermal nociception in normal rats and did not alter motor performance at analgesic doses. These data

demonstrate that selective blockade of P2X₇ receptors *in vivo* produces significant antinociception in animal models of neuropathic and inflammatory pain.

Introduction

P2X₇ receptors belong to the family of ATP-sensitive ionotropic P2X receptors, which are composed of seven receptor subtypes (P2X₁ – P2X₇) (North, 2002). Unlike other members of the P2 receptor superfamily, homomeric P2X₇ receptors are activated by high concentrations of ATP (> 100 μM) and 2', 3'-O-(4-benzoylbenzoyl)-ATP (BzATP) has significantly greater potency (EC₅₀ = 20 μM) than ATP (EC₅₀ > 100 μM) (Jacobson et al., 2001). P2X₇ receptors are found predominantly on macrophages and other cells of immunological origin where they can trigger a series of cellular responses such as membrane permeabilization, activation of caspases, cytokine release, cell proliferation, and apoptosis (Panenka et al., 2001; Chakfe et al., 2002; North, 2002; Verhoef et al., 2003; Kahlenberg and Dubyak, 2004). In addition to agonist-induced changes in intracellular calcium concentrations, activation of P2X₇ receptors stimulates caspase-1 activation, release of interleukin-1β (IL-1β), and activation of p38 mitogen activated protein kinase (MAPK) (Armstrong et al., 2002; Ferrari et al., 2006). Another feature of P2X₇ receptors is that prolonged agonist exposure leads to the formation of large cytolytic pores in cell membranes (Suprenant et al., 1996). The underlying mechanisms and functional significance of P2X₇-mediated pore formation remain to be elucidated; however P2X₇-mediated pore formation is dependent on intracellular signaling events involving, at least in part, p38 MAPK and caspase-1 (Pannicke et al., 2000; North, 2002; Donnelly-Roberts et al., 2004).

Both the localization of P2X₇ receptors on pro-inflammatory cells and the demonstration that activation of P2X₇ receptors modulates the release of IL-1 have implicated a role for this P2X receptor in inflammatory diseases (North, 2002; Baraldi et al., 2003). A pro-inflammatory role for P2X₇ receptors in inflammation was further supported by the demonstration that P2X₇ knockout mice showed reduced inflammation in an experimental passive collagen induced-arthritis model (Labasi et al., 2002). More recently, it was demonstrated that P2X₇ knockout mice also show reduced inflammatory thermal hyperalgesia and nerve injury induced mechanical allodynia as compared to matched wild type mice (Chessell et al., 2005).

While the expression of P2X₇ receptors has been reported in brain, microglia, and astrocytes based on immunoreactivity studies (Collo et al., 1997; Sim et al., 2004), considerable controversy exists regarding the existence of functional P2X₇ receptors on peripheral and central neurons due to the poor specificity of primary antibodies and ligands targeting the rat P2X₇ receptor (Anderson and Nedergaard, 2006). However, functional P2X₇ receptors have been demonstrated on peripheral glial cells in rat dorsal root ganglion and this expression may play a role in peripheral sensory transduction of pain perception (Zhang et al., 2005). The present study describes the pharmacological characterization of A-740003 (Figure 1), a structurally novel and highly specific antagonist for mammalian P2X₇ receptors that dose-dependently reduces nociception in rodent models of neuropathic and inflammatory pain.

Materials and Methods

In vitro characterization of A-740003

Materials: The following were purchased from Sigma (St. Louis, MO): BzATP, 2,3-O-(4-benzoylbenzoyl)-ATP; PPADS, pyridoxal phosphate-6-azophenyl-2-4-disulfonic acid; and Brilliant Blue G. KN-62, 1-[N,O-bis(5-isoquinolinesulfonyl)-N-methyl-L-tyrosyl]-4-phenylpiperazine was purchased from Tocris (Ellisville, MO). Fluo-4 dye was purchased from TEF Labs (Austin TX) and Yo-Pro-1(4-[(3-methyl-2(3H)-benzoxazolylidene)methyl]-1[3-(trimethylammonio)propyl]-diiodide was purchased from Invitrogen (Eugene, OR). All cell culture medium and Dulbecco's phosphate buffered saline (DPBS), pH 7.4 were also obtained from Invitrogen (Grand Island, NY).

Cell culture. 1321N1 human astrocytoma cells stably expressing either human and rat P2X₇, human P2X₄, P2X_{2a}, P2X_{2/3}, P2X₁, P2Y₁ and P2Y₂ recombinant receptors were grown according to previously published protocols (Bianchi et al., 1999; Lynch et al., 1999). Briefly, 1321N1 cells expressing transfected P2 receptors were maintained in a humidified 5% CO₂ atmosphere at 37°C in Dulbecco's Modified Eagle Medium (DMEM) containing 1% L-Alanyl-L-Glutamine, 1% Antibiotic/Antimycotic, 10% fetal bovine serum (FBS), and 300 µg/ml Geneticin. 1321N1 P2X_{2a} cells were grown in DMEM containing 1% L-Alanyl-L-Glutamine, 1% Antibiotic/Antimycotic, 10% FBS, and 100 µg/ml hygromycin B. 1321N1 P2X_{2a/3} cells were maintained in growth medium containing 150 µg/ml Geneticin and 75 µg/ml hygromycin B. Cells of the THP-1 monocytic cell line (American Type Culture Collection, Rockville,

MD) were maintained in the log phase of growth in RPMI medium containing high glucose and 10% fetal calf serum (Invitrogen, Grand Island, NY) according to established procedures (Humphrey and Dubyak, 1996). Fresh vials of frozen THP-1 cells were initiated for growth every eight weeks. To differentiate THP-1 cells into a macrophage phenotype, a final concentration of 25 ng/ml of LPS and 10 ng/ml of IFN γ were added to the cells (Humphrey and Dubyak, 1996) either for 3 hours for IL-1 β release assays or overnight (16 hours) for pore formation studies.

Ca⁺² Influx Assay. Agonist-induced changes in intracellular Ca⁺² concentrations were assessed in all of the cell lines using the Ca⁺² chelating dye, Fluo-4 in conjunction with a Fluorometric Imaging Plate Reader (FLIPR; Molecular Devices, Sunnyvale, CA) as previously described (Bianchi et al., 1999) with minor modifications. The cells were plated out the day before the experiment onto Poly-D-Lysine coated black 96 well plates (Becton-Dickinson, Bedford, MA and Sigma, St. Louis MO). Cell concentration was 5 x 10⁶ cells per plate. Fluo-4 was dissolved in anhydrous DMSO to a final concentration of 5 μ M in DPBS. The dye was loaded onto the adherent cells and the plates were centrifuged for 5 minutes at 1000 rpm. Cells were loaded for at least one hour, but not more than 3 hours and kept in the dark at room temperature. After loading, the unincorporated Fluo-4 was removed by washing with DPBS using a SkanWasher 400 (Molecular Devices, Sunnyvale, CA). All compound solutions were prepared in DPBS. After the agonist addition, changes in intracellular Ca²⁺ concentrations were recorded on a second time scale for 3

minutes. Ligands were tested at 11 half-log concentrations from 10^{-10} to 10^{-4} M. Independent measurements of a positive control (100%) were performed on each plate in order to normalize values from plate to plate. Agonist concentrations corresponded to their relative EC_{70} values for each receptor to enable comparison of antagonist potencies across multiple P2 receptor subtypes (Jarvis et al., 2002). Since P2X_{2/3} receptors have an identical pharmacological profile as homomeric P2X₃ receptors and do not rapidly desensitize (Jarvis et al., 2004), the heteromeric receptor was used for selectivity versus P2X₃ receptors. Structural analogs of A-740003, as well as other structurally diverse P2X₇ antagonists (Nelson et al., 2006) did not activate homomeric P2X₃ receptors at concentrations up to 10 μ M (Donnelly-Roberts, unpublished observations). For measurement of antagonist activity, ligands were added to the cell plate and fluorescence data collected for 3 minutes before the addition of the agonist. Fluorescence data was collected for another 2 minutes after the agonist addition. Concentration-response data were analyzed using GraphPad Prism (San Diego, CA); the pEC_{50} or pIC_{50} values were derived from a single curve fit to the mean data of n=4-6, in duplicates.

Yo-Pro Uptake Assay. Agonist-induced pore formation was assessed using uptake of Yo-Pro dye (MW=629; Invitrogen: Molecular Probes, Eugene, OR) in the recombinant rat, human P2X₇-1321N1 cell lines or differentiated THP-1 cells as previously described (Donnelly-Roberts et al., 2004). Yo-Pro iodide dye (1 mM in 100% DMSO) was diluted to a final concentration of 2 μ M in PBS

(w/o Mg^{2+} or Ca^{2+}) and then placed on the cells immediately prior to agonist addition. Cells were plated the day before at a density of 1×10^6 cells/ plate onto poly-D-lysine-coated black-walled 96-well plates to reduce light scattering. For differentiated THP-1 (25 ng/ml LPS and 10 ng/ml IFN γ , overnight), the cells were plated onto poly-D-lysine-coated black-walled 96-well plates to $1-2 \times 10^6$ cells /ml / well. After the addition of various concentrations of agonists, the Yo-Pro dye uptake was observed in the FLIPR by capturing the intensity of fluorescence by the CCD camera every 15 seconds for the first 10 minutes of agonist exposure followed by every 20 seconds for an additional 50 minutes. For antagonist activity measurements, the percent maximal intensity was normalized to that induced by an EC $_{70}$ concentration for BzATP activation and plotted against the antagonist compound concentration to calculate IC $_{50}$ values and account for plate-to-plate variability. Concentration-response data were analyzed using GraphPad Prism (San Diego, CA); the pEC $_{50}$ or pIC $_{50}$ values were derived from a single curve fit to the mean data of n=6 in duplicates.

IL-1 β release in THP-1 cells: In the presence of the differentiation media, THP-1 cells were incubated with inhibitors for 30 minutes at 37°C followed by a challenge with 1 mM BzATP for an additional 30 min at 37°C. Supernatants were collected after a 5 min centrifugation in microfuge tubes and assayed for the presence of mature IL-1 β by ELISA (Endogen, Rockford IL), following the manufacturer's instructions. For each experiment, differentiated control cells were also measured over the 60 min time course of the assay to assess background IL-1 β accumulation. This non-specific background IL-1 β release,

which typically averaged 3-8% of the maximum BzATP response, was subtracted from the maximum BzATP-induced release.

In Vivo Pain Models and Pharmacokinetic profile

Subjects. Male Sprague-Dawley rats (Charles River, Wilmington, MA) weighing 200-300 grams were utilized in all experiments. Animals were group-housed in AAALAC approved facilities at Abbott Laboratories in a temperature-regulated environment with lights on between 0700 and 2000 hours. Food and water were available *ad libitum* except during testing. All animal handling and experimental protocols were approved by an institutional animal care and use committee (IACUC). All experiments were performed during the light cycle.

Acute Thermal Nociception. The response to acute thermal stimulation was determined using a commercially available paw thermal stimulator (UARDG, University of California, San Diego, CA). Rats were placed individually in Plexiglas cubicles mounted on a glass surface maintained at 30°C, and allowed a 30 min habituation period. A thermal stimulus, in the form of radiant heat emitted from a focused projection bulb, was then applied to the plantar surface of each hind paw. In each test session, each rat was tested in 3 sequential trials at approximately 5 min intervals. Paw withdrawal latencies (PWL) were calculated as the median of the two shortest latencies. An assay cut off was set at 20.5 seconds. A-740003 was injected i.p. 30 minutes before testing for acute thermal pain.

Carrageenan and Complete Freund's Adjuvant-induced Thermal Hyperalgesia and Edema. Unilateral inflammation was induced by injecting 100 μ l of a 1% solution of λ -carrageenan or 150 μ l of a 50% solution of complete Freund's adjuvant (CFA) (Sigma Chemical Co., St. Louis, MO) in physiological saline into the plantar surface of the right hind paw of the rat. The hyperalgesia to thermal stimulation was determined 2hr or 48hr following carrageenan or CFA injection, respectively, using the same apparatus as described above for the noxious acute thermal assay. In addition, in both models, the volume of paw edema was measured using water displacement with a plethysmometer (Buxco, Sharon, CT) by submerging the hind paw up to the ankle hairline (approximately 1.5 cm). The volume of water displacement was measured by a transducer and recorded by a computer. A-740003 was injected 90 minutes following carrageenan injection (i.e. 30 minutes before testing in inflamed rats). In the CFA experiments, CFA was injected 2 days before testing. On the day of testing, A-740003 was injected 30 minutes (i.p.) before testing for thermal hyperalgesia.

Spinal Nerve (L5/L6) Ligation Model of Neuropathic Pain. As previously described in detail by Kim and Chung (1992), a 1.5 cm incision was made dorsal to the lumbosacral plexus in anesthetized rats. The paraspinal muscles (left side) were separated from the spinous processes, the L5 and L6 spinal nerves isolated, and tightly ligated with 3-0 silk threads. Following hemostasis, the wound was sutured and coated with antibiotic ointment. The rats were allowed to recover and then placed in a cage with soft bedding for 14 days

before behavioral testing for mechanical allodynia. A-740003 was injected i.p. 30 minutes before testing for mechanical allodynia.

Mechanical (tactile) allodynia was measured using calibrated von Frey filaments (Stoelting, Wood Dale, IL). Briefly, rats were placed into individual Plexiglas containers and allowed to acclimate for 15-20 minutes before testing. Paw withdrawal threshold (PWT_{vonfrey}) was determined by increasing and decreasing stimulus intensity and estimated using a Dixon non-parametric test. Only rats with threshold scores ≤ 4.5 g were considered allodynic and utilized in compound testing experiments.

Sciatic Nerve Ligation Model of Neuropathic Pain. As previously described in detail by Bennett and Xie (1988), in anesthetized rats, a 1.5 cm incision was made 0.5cm below the pelvis and the biceps femoris and the gluteous superficialis (right side) were separated. The sciatic nerve was exposed, isolated, and four loose ligatures (5-0 chromic catgut) with 1 mm spacing were placed around it. The rats were allowed to recover and then placed in a cage with soft bedding for 14 days before behavioral testing for mechanical allodynia as described above. A-740003 was injected i.p. 30 minutes before testing for mechanical allodynia.

Chemotherapy-induced Neuropathic Pain. As previously described in detail by Lynch et al (2004), chemotherapy-induced neuropathic pain was induced by a continuous i.v. infusion of vincristine. In anesthetized rats, the right external jugular vein was catheterized (PE60 tubing) with a vincristine filled osmotic pump (0.5 $\mu\text{l/h}$, 14 days; Alzet Model 2002, Durect Corporation, Cupertino, CA)

that had been primed overnight to deliver 30 $\mu\text{g}/\text{kg}/\text{day}$ vincristine sulfate (Sigma-Aldrich, St Louis, MO). The rats were allowed to recover and then placed in a cage with soft bedding for 14 days before behavioral testing for mechanical allodynia as described above. A-740003 was injected i.p. 30 minutes before testing for mechanical allodynia. In this model because of the bilateral allodynia, maximal possible effects were set at 15 g.

Rotorod Performance. Rotorod performance was measured using an accelerating rotorod apparatus (Omnitech Electronics, Inc. Columbus, OH). Rats were allowed a 30 min acclimation period in the testing room and then placed on a 9 cm diameter rod that increased in speed from 0 to 20 rpm over a 60 sec period. The time required for the rat to fall from the rod was recorded, with a maximum score of 60 sec. Each rat was given 3 training sessions. Rotorod performance (latencies to fall from the rotorod) was determined 30 minutes following A-740003 injection (i.p.).

Compounds. A-740003 (N-(1-[(cyanoimino)(5-quinolinylamino) methyl]amino)-2,2-dimethylpropyl)-2-(3,4-dimethoxyphenyl)acetamide, Figure 1) was synthesized at Abbott Laboratories. A-740003 was dissolved in 30% NMP (N-methylpyrrolidinone), 30% polyethylene glycol (PEG400), 40% hydroxypropyl- β -cyclodextrin for intraperitoneal (i.p.) administration 30 minutes before testing and in 100% PEG400 for oral (p.o.) administration 60 minutes before testing in a 2ml/kg dosing volume. As part of an ongoing drug discovery program, doses of A-740003 ranged from 10-300 $\mu\text{mol}/\text{kg}$ for relative comparisons of

compound potency. Doses of A-74003 used in the *in vivo* studies are expressed as mg/kg in this report for clarity.

Statistics. Analysis of the *in vivo* data was carried out using analysis of variance. Where appropriate, Fisher's Protected Least Significant Difference (FPLSD) was used for post-hoc analysis. The level of significance was set at $p < 0.05$. ED_{50} values were estimated using least squares linear regression. Data are presented as mean \pm S.E.M.

Results

A-740003 potently blocks P2X₇ Receptors. A-740003 potently blocked BzATP evoked changes in intracellular calcium concentrations in 1321N1 cells stably expressing rat (IC₅₀ =18 nM) or human (IC₅₀ = 40 nM) P2X₇ receptors (Figure 2). For comparison, PPADS, Brilliant Blue G (rat selective P2X₇ antagonist), and KN-62 (a human selective P2X₇ antagonist; Anderson and Nedergaard, 2006) were significantly less potent in blocking BzATP-evoked changes in intracellular calcium concentrations (Figure 2 and Table 1). A-740003 also blocked BzATP-mediated pore formation as measured by the intracellular uptake of YoPro (Figure 3) at both the rat (IC₅₀ = 138 nM) and human (IC₅₀ = 93 nM) P2X₇ receptors. A-740003 was significantly more potent in blocking P2X₇-mediated pore formation as compared to PPADS, KN62 or Brilliant Blue G (Table 1 and Figure 3).

A-740003 blocks P2X₇ Receptors on Differentiated Human THP-1 Cells.

Human THP-1 cells differentiated with LPS and IFN γ into a macrophage phenotype express P2X₇ receptors and receptor activation lead to IL-1 β release as well as Yo-Pro uptake (Humphrey and Dubyak, 1996; Donnelly-Roberts et al., 2004). A-740003 potently blocked Yo-Pro uptake in differentiated human THP-1 cells (IC₅₀ of 92 nM) (Figure 4). A-740003 also blocked IL-1 β release in the THP-1 cells (IC₅₀ of 156 nM) (Figure 4).

A-740003 Is A Highly Selective P2X₇ Antagonist. As shown in Figure 5, A-740003, at concentrations up to 100 μ M, did not significantly reduce agonist-evoked changes in intracellular calcium concentrations mediated by a variety

of other P2X and P2Y receptors. We have previously demonstrated that there is a high positive correlation ($r = 0.98$) between ligand binding at heteromeric P2X_{2/3} receptors and homomeric P2X₃ receptors (Jarvis et al., 2004). Consequently, A-740003 was not tested at homomeric P2X₃ receptors since it was inactive at P2X_{2/3} receptors. Other analogs of A-740003, as well as other structurally novel P2X₇ receptor antagonists (Nelson et al., 2006) did not significantly interact at homomeric P2X₃ receptors at concentrations up to 10 μ M (Donnelly-Roberts, unpublished observations). A-740003 was also evaluated for its ability to interact with a large array of G-protein-coupled receptors, enzymes, transporters, and ion channels (CEREP, Poitiers, France; www.cerep.fr/cerep/users/pages/catalog/assay) (Table 2). A-740003 showed weak or no activity in all of these assays ($IC_{50} > 5 \mu$ M).

A-740003 Is a Competitive Antagonist at the P2X₇ Receptor. To determine the nature of the antagonism of P2X₇ receptors by A-740003, BzATP concentration-effect curves were determined in the presence of increasing concentrations of A-740003. Figure 6 shows that BzATP concentration-effect curves were shifted to the right with increasing A-740003 concentrations, without affecting the maximal BzATP response in control wells. These results indicated that A-740003 acts as a competitive antagonist at the P2X₇R BzATP binding site. Analysis of these data generated a pA₂ value of 7.34 and a slope factor of 0.98 ± 0.16 (Figure 6).

Pharmacokinetic Profile of A-740003. The pharmacokinetic (PK) profile of A-740003 in rats (Figure 7) was characterized by high plasma clearance (CL_p

= 3.7 L/hr·kg), moderate oral bioavailability ($F = 20\%$), a high volume of distribution ($V_{\beta} = 21$ L/kg), and a long plasma elimination half-life ($T_{1/2} = 4.0$ h, i.v.). The maximal plasma concentration (C_{max}) and time to maximal plasma concentration (T_{max}) following oral administration at 2 mg/kg were 0.13 $\mu\text{g/ml}$ and 2.5 hours, respectively. In addition, A-740003 had good bioavailability ($F = 79\%$) following intraperitoneal administration at 2.3 mg/kg with a C_{max} of 0.76 $\mu\text{g/ml}$ and a T_{max} of 0.25 hours. Plasma and spinal cord samples were harvested 30 minutes following i.p. administration. Mean plasma levels of A-740003 were 5.5 ± 1.2 $\mu\text{g/ml}$ at 14.2 mg/kg and 18.4 ± 4.6 $\mu\text{g/ml}$ at 47.4 mg/kg and brain levels were 0.6 ± 0.2 $\mu\text{g/g}$ at 14.2 mg/kg and 1.0 ± 0.3 $\mu\text{g/g}$ at 47.4 mg/kg.

Spinal Nerve Injury-induced Mechanical Allodynia. L5-L6 spinal nerve ligation, (SNL; Kim and Chung, 1992) induced a decrease in $\text{PWT}_{\text{vonfrey}}$ to mechanical stimulation with von Frey monofilaments 2 weeks following injury ($\text{PWT}_{\text{vonfrey}}$ control 12.9 ± 0.4 g, $\text{PWT}_{\text{vonfrey}}$ injured 2.9 ± 0.1 g, $p < 0.01$) demonstrating the development of mechanical allodynia. A-740003 reversed SNL-induced mechanical allodynia in a dose-related manner (ED_{50} of 19 mg/kg, i.p.) with 64.9 ± 11.1 % effect at the highest dose tested (Figure 8, Table 3). In addition, in another set of allodynic SNL animals ($\text{PWT}_{\text{vonfrey}}$ control 13.2 ± 0.4 g, $\text{PWT}_{\text{vonfrey}}$ injured 3.7 ± 0.1 g, $p < 0.01$), A-740003 reduced SNL-induced mechanical allodynia following oral administration with 37.1 ± 9.5 % increase in PWT at 142.4 mg/kg, p.o. ($\text{PWT}_{\text{vonfrey}}$ 7.8 ± 0.9 g, $p < 0.01$ vs vehicle treated animals $\text{PWT}_{\text{vonfrey}}$ injured 4.3 ± 0.4 g).

Sciatic Nerve Injury-induced Mechanical Allodynia. Chronic constriction injury of the sciatic nerve (CCI; Bennett and Xie, 1998) produced a decrease in PWT_{vonfrey} to mechanical stimulation with von Frey monofilaments 2 weeks following surgery (PWT_{vonfrey} control 13.3 ± 0.3 g, PWT_{vonfrey} injured 2.9 ± 0.1 g, $p < 0.01$) demonstrating the development of mechanical allodynia. A-740003 attenuated CCI-induced mechanical allodynia in a dose-related manner with an ED_{50} of 114 mg/kg, i.p. and efficacy of 54.7 ± 14.3 % at the highest dose tested (Figure 9A, Table 3).

Chemotherapy-induced Mechanical Allodynia. Continuous vincristine infusion produced a decrease in PWT_{vonfrey} to mechanical stimulation with von Frey monofilaments 2 weeks following the beginning of the infusion (PWT_{vonfrey} control 15.0 ± 0.0 g, PWT_{vonfrey} injured 3.7 ± 0.1 g, $p < 0.01$) demonstrating the development of mechanical allodynia. A-740003 attenuated vincristine-induced mechanical allodynia in a dose-related manner with 50.8 ± 6.4 % effect at the highest dose tested (Figure 9B, Table 3).

Carrageenan-induced Acute Inflammatory Thermal Hyperalgesia and Edema. Carrageenan injection into the hind paw induced a significant decrease in PWL to thermal stimulation (PWL control: 9.9 ± 0.2 sec vs. PWL inflamed: 2.3 ± 0.1 sec, $p < 0.01$), demonstrating the development of thermal hyperalgesia 2 hours following carrageenan injection (Figure 10A). A-740003 reduced carrageenan-induced thermal hyperalgesia in a dose-related manner (ED_{50} of 54 mg/kg, i.p.) with 75 ± 5 % antinociceptive effect at the highest dose tested (Figure 8A). Under the same conditions, A-740003 had no effect on

PWL of the contralateral non-inflamed paw, indicative of a specific anti-hyperalgesic effect in this model.

The acute anti-inflammatory effects of A-740003 were assessed in the carrageenan-induced paw edema model. A-740003 (14 -142 mg/kg, i.p.) attenuated carrageenan-induced paw edema ($F(3;47)=4.75$, $p < 0.01$). At 142 mg/kg, i.p., A-740003 produced a 36 ± 7 % decrease in paw volume ($p < 0.01$, Table 3).

CFA-induced Chronic Inflammatory Thermal Hyperalgesia and Edema.

CFA injection into the hind paw induced a significant decrease in PWL to thermal stimulation 48 hours following CFA injection (PWL control: 10.2 ± 0.3 sec vs. PWL inflamed: 5.6 ± 0.1 sec, $p < 0.01$), demonstrating the development of thermal hyperalgesia (Figure 10B). A-740003 attenuated CFA-induced thermal hyperalgesia in a dose-related manner (ED_{50} of 38 mg/kg, i.p.) with 58.7 ± 16.5 % effect at the highest dose tested (Figure 10B). Under the same conditions, A-740003 had no effect on PWL of the contralateral non-inflamed paw, indicative of a specific antihyperalgesic effect in this model.

The acute anti-inflammatory effects of A-740003 were also assessed in the CFA-induced paw edema model. A-740003 (14 -142 mg/kg, i.p.) did not significantly decrease CFA-induced paw edema ($F(3;35)=2.28$, $p > 0.05$, Table 3).

Acute Thermal Pain. A-740003 did not produce significant antinociception on acute thermal pain in naïve rats. A-740003 (142 mg/kg, i.p.) treated animals

had a PWL to acute thermal stimulation of 10.9 ± 0.1 seconds compared to 10.9 ± 0.5 in vehicle-treated animals ($p > 0.05$, Table 3).

Effects on Motor Activity and General CNS Function. A-740003 had no significant effect on motor coordination at doses up to 142 mg/kg, i.p. ($F(3,31)=0.35$, $p > 0.05$), as measured by the ability of rats to run on an accelerating rotating rod (latency to fall for the control group = 58.1 ± 1.0 sec; for the highest dose group = 56.3 ± 3.1 sec). Rats were fully awake, responsive to stimuli, and retained the righting reflex, consistent with their ability to perform the rotorod test at all doses tested.

Discussion

The present data demonstrate that A-740003 is a potent antagonist of rat and human P2X₇ receptors. A-740003 blocked P2X₇ receptor mediated changes in intracellular calcium concentrations in a competitive fashion and was highly selective as compared to its activity at other P2 receptors as well as other cell surface receptors and ion channels. A-740003 also potently blocked other consequences of P2X₇ receptor activation including BzATP-evoked IL-1 β release in differentiated human THP-1 cells and prolonged agonist stimulated pore formation.

The discovery of A-740003 represents a significant advance in P2X receptor pharmacology since this compound is both more potent and more selective than other previously described P2X₇ receptor antagonists (Romagnoli et al., 2005). A-740003 also shows much less species differences in its ability to block both rat and human P2X₇ receptors as compared to the rat selective antagonist, BBG and the human selective antagonist KN-62 (Anderson and Nedergaard, 2006). It is interesting to note that both of the latter antagonists are more than 10-fold more potent to block P2X₇ receptor mediated pore formation (Yo-Pro uptake) as compared to their ability to block receptor mediated calcium influx. The differential potency of these antagonists to block these P2X₇ receptor mediated effects has been attributed to their relatively slow association kinetics in the two different assays (Namovic et al., 2005). In contrast, A-740003 showed equivalent potency to block both human P2X₇ receptor-mediated changes in intracellular calcium concentrations and

Yo-Pro uptake. Similarly, an analysis of a series of novel phenyltetrazole-based P2X₇ antagonists (Nelson et al., 2006) indicates that antagonism of P2X₇ receptor-mediated changes in intracellular calcium concentrations, IL-1 β release, and Yo-Pro uptake are positively correlated.

The activation of P2X₇ receptors results in the rapid maturation and extracellular release of the pro-inflammatory cytokine, IL-1 β (Perregaux et al., 1994; Solle et al., 2001; Ferrari et al., 2006). Other biochemical consequences of increased IL-1 β concentrations include induction of nitric oxide synthase as well as increased production of cyclooxygenase-2 and tumor necrosis factor- α (TNF- α ; Woolf et al., 1997; Samad et al., 2001; Parvathenani et al., 2003). All of these pro-inflammatory events can also contribute to enhanced pain sensitivity (Woolf et al., 1997; Burnstock, 2006). The physiological significance of P2X₇ receptor modulation of IL- β release is evidenced by the reduced inflammatory phenotype of P2X₇ knockout mice (Labasi et al., 2002; Solle et al., 2001). ATP stimulation of macrophages from P2X₇ knockout mice does not result in the release of mature IL-1 β and P2X₇ knockout mice show significantly diminished inflammation in an experimental passive collagen induced-arthritis model (Labasi et al., 2002). A more recent study has demonstrated that P2X₇ knockout mice show reduced pain sensitivity following both complete Freund's adjuvant-induced inflammation and partial injury of the sciatic nerve (Chessell et al., 2005).

Similar to the nociceptive phenotype of mice lacking P2X₇ receptors (Chessell et al., 2005) or lacking both isoforms of IL-1 (Honore et al., 2006),

systemic administration of A-740003 produced dose-dependent antinociceptive effects in models of neuropathic pain and inflammatory pain. A-740003 was particularly potent at reducing mechanical allodynia observed 2 weeks following L5/L6 nerve ligation. The antinociceptive activity of A-740003 in this model of neuropathic pain is consistent with recent reports of the analgesic efficacy of two other structurally distinct P2X₇ antagonists (Lappin et al., 2005; Nelson et al., 2006). A-740003 also significantly attenuated mechanical allodynia in two additional models of neuropathic pain: chronic constriction injury of the sciatic nerve and vincristine-induced neuropathic pain. The exact reasons for the differential potency of A-740003 to reduce tactile allodynia in these neuropathic pain models is unknown. However, these data may illustrate the preferential role of P2X₇ receptor modulation of IL-1 β in reducing nociception in the SNL model as compared to the robust analgesic efficacy of a P2X₃ antagonist to reduce neuropathic allodynia in the chronic constriction injury of the sciatic nerve model (Jarvis et al., 2002).

A-740003 also significantly reduced thermal hyperalgesia in two models of inflammatory pain: intraplantar administration of complete Freund's adjuvant or carrageenan. The robust antinociceptive effects of A-740003 in these inflammatory pain models does not appear to be secondary to an anti-inflammatory effect since A-740003 was more efficacious at reducing nociception compared to paw edema in both of these models. It should be noted, however, that the anti-inflammatory activity of P2X₇ antagonists may be more pronounced in arthritis models as compared to acute (carrageenan) and

sub-acute (CFA) inflammatory models where the contribution of IL-1 β to ongoing inflammatory processes may be more prominent in chronic arthritis (Labasi et al., 2002).

Collectively, the present data and the phenotype of the P2X₇ knockout mice indicate a specific role for P2X₇ receptor activation in chronic pain states. It should be noted that Dell'Antonio et al. (2002a,b) have reported that local administration of oxidized-ATP (oATP), a weak and irreversible antagonist of P2X₇ receptors (Suprenant et al., 1996), reduced inflammation-induced mechanical hyperalgesia in rats. While these investigators attributed these results to blockade of P2X₇ receptors, it must be appreciated that oATP has weak affinity for P2X₇ receptors and also has many other pharmacological actions including blockade of P2X₁ and P2X₂ receptors (Evans et al., 1995) and inhibition of nuclear factor NF- κ B and cytokine release (Di Virgilio, 2006; Murgia et al., 1993; Beigi et al., 2003). Consequently, the use of o-ATP to block nociceptive responses *in vivo* cannot be taken as evidence for a specific role of P2X₇ in nociceptive signaling (Chessell et al., 2005; Anderson and Nedergaard, 2006).

The antinociceptive effects of A-740003 in chronic pain states are consistent with the mechanistic role of P2X₇ receptors in modulating IL-1 β release and the ability of this pro-nociceptive cytokine to alter pain sensitivity in animal models. In addition to its pro-inflammatory effects, endogenous IL-1 levels are increased in the CNS in response to trauma associated with mechanical damage, ischemia, seizures, and hyperexcitability (Touzani et al.,

2002). Increased IL-1 concentrations in the CNS also result in dose-dependent modulation of nociceptive signaling (Bianchi et al., 1998, Horai et al., 2000). At the level of the spinal cord, blockade of IL-1 receptors with the IL-1 receptor antagonist (IL-1ra), results in reduced nociception in animal models of inflammation and nerve-injury induced pain (Maier et al., 1993; Safieh-Garabedian et al., 1995; Sommer et al., 1999). These findings are further supported by the demonstration that exogenously applied IL-1 produces hyperalgesia when applied peripherally (Ferreira et al., 1988). In addition to the analgesic effects of the IL-1ra in experimental pain models, several genetic approaches have been used to further investigate the pronociceptive actions of IL-1 in mice. These include targeted gene disruption of the IL-1 Type I receptor or the *IL-1acp*, as well as, transgenic over-expression of the IL-1ra (Wolf et al., 2004) or IL-1 $\alpha\beta$ double knockout (Honore et al., 2006). All of these approaches have produced mice that show reduced nociceptive responses relative to wild-type animals. Collectively, these data clearly indicate that P2X₇ receptor modulation of IL-1 contributes to nociceptive sensitivity in chronic pain states.

The present data further illustrate the multitude of mechanisms by which ATP can alter nociceptive sensitivity following tissue injury (Burnstock and Wood, 1996). Evidence from a variety of experimental strategies including genetic disruption and the development of selective antagonists has indicated that activation of several P2X receptors, including P2X₃, P2X_{2/3}, P2X₄ and P2X₇, and P2Y (e.g. P2Y₂) receptors can modulate pain. For example, A-

317491, a selective P2X₃ antagonist (Jarvis et al., 2002) effectively blocks both CFA-induced inflammatory thermal hyperalgesia as well as mechanical and thermal hyperalgesia resulting from chronic constriction of the sciatic nerve. Intrathecally delivered antisense oligonucleotides specifically targeting P2X₄ receptors have been shown to decrease tactile allodynia following nerve injury (Tsuda et al., 2003). In addition, activation of P2Y₂ receptors leads to sensitization of TRPV1 receptors (Tominaga et al., 2001; Lakshmi and Joshi, 2005). Thus, ATP acting at multiple purinergic receptors either directly on neurons (e.g. P2X₃, P2X_{2/3} and P2Y receptors) or through indirect neural-gial cell interactions (P2X₄ and P2X₇) can alter nociceptive sensitivity (Tsuda et al., 2003; Zhang et al., 2005).

Taken together, the present data demonstrate that the acute *in vivo* blockade of P2X₇ receptors significantly reduces nociception in animal models of persistent neuropathic and inflammatory pain. While there is growing appreciation for the role of P2X₇ modulation of pro-inflammatory IL-1 processing (Ferrari et al., 2006), the analgesic activity of A-740003, and other recently described selective P2X₇ receptor antagonists (Nelson et al., 2006), suggests a specific role for P2X₇ in neural-gial cells interactions associated with ongoing pain (Zhang et al., 2005).

Figure 1. Structure of A-740003, (N-(1-[[[(cyanoimino)(5-quinolinylamino)methyl]amino]-2,2-dimethylpropyl]-2-(3,4-dimethoxyphenyl)acetamide.

Figure 2. A-740003 potently blocks rat and human P2X₇ receptors. A-740003 blocked BzATP-mediated changes in intracellular calcium concentrations at (A) rat (10 μ M BzATP) and (B) human (5 μ M BzATP) P2X₇ receptors. PPADS and BBG were significantly less potent and KN62 showed no activity (Table 1) to block rat P2X₇ receptors. Similarly, PPADS and KN62 were significantly less potent and BBG showed no activity (Table 1) to block human P2X₇ receptors. Data are represented in percentage of maximal response (control) minus basal fluorescence. See Table 1 for a summary of the pIC₅₀ values.

Figure 3. A-740003 potently blocks pore formation mediated by rat and human P2X₇ receptors. A-740003 blocked BzATP-mediated Yo-Pro uptake at (A) rat (7.5 μ M BzATP) and (B) human (2.5 μ M BzATP) P2X₇ receptors. PPADS and BBG were significantly less potent and KN62 showed negligible activity (Table 1) to block rat P2X₇ receptors. Similarly, KN62 was slightly less potent versus PPADS and BBG, which had weaker activity (Table 1) to block human P2X₇ receptors. Data are represented in percentage of maximal response (control) minus basal fluorescence. See Table 1 for a summary of the pIC₅₀ values.

Figure 4. A-740003 potently blocks native human P2X₇ receptors expressed in differentiated THP-1 cells. A-740003 blocked 90 μ M BzATP-mediated changes in both pore formation (\square) or IL-1 β release (\bullet) in differentiated human THP-1 by addition of the antagonist 30 minutes before agonist stimulation with BzATP, as described under Materials and Methods. Data are represented as percentage of maximal response (control) minus basal fluorescence.

Figure 5. A-740003 is a highly selective P2X₇ antagonist. A-740003 selectively blocks P2X₇ receptors and not other P2 subtypes. ATP (4 μ M) was used to activate P2X₁, P2X₄, and P2Y₁ receptors and ATP (10 μ M) was used for P2X_{2a} and P2X_{2a/3} receptors. UTP (1 μ M) was used to activate P2Y₂ receptors. BzATP (5 μ M) was used for human P2X₇ receptors. Data are represented in percentage of maximal response (control) minus basal fluorescence.

Figure 6. A-740003 is a competitive antagonist at the P2X₇ receptor. A. Concentration effect curves for BzATP-induced increases intracellular calcium concentrations were generated in the presence of increasing concentrations of A-740003. Curves are plotted as percent relative to the maximal response in the absence of A-740003. B. Schild plot analysis of the antagonism produced by A-740003 with a slope = 0.98 ± 0.16 and a pA₂ of 7.4.

Figure 7. Pharmacokinetic profile of A-740003 (5 μ mol/kg, i.v., i.p., and p.o.) in rats. The pharmacokinetic profile of A-740003 in rats was characterized by a high plasma clearance (CL_p = 3.7 L/hr·kg), moderate oral bioavailability (F = 20%), a high volume of distribution (V_β = 21 L/kg), and a long plasma elimination half-life (T_{1/2} = 4.0 h, i.v.). C_{max} and T_{max} following oral administration at 2 mg/kg were 0.13 μ g/ml and 2.5 hours, respectively. In addition, A-740003 had good bioavailability (F = 79%) following intraperitoneal administration at 2.3 mg/kg with a C_{max} of 0.76 μ g/ml and a T_{max} of 0.25 hours.

Figure 8. Antinociceptive effects of A-740003 in the spinal nerve ligation model of neuropathic pain. Two weeks following L5-L6 spinal nerve injury A-740003 was injected 30 minutes (i.p.) before testing. A-740003 demonstrated significant antiallodynic effects in neuropathic pain (F(5;152)=109.42, p < 0.0001). Circles represent paw withdrawal threshold ipsilateral to the injury. Data represent mean \pm S.E.M. ** p < 0.01 as compared to vehicle-treated animals (n = 6-12 per group).

Figure 9. Antinociceptive effects of A-740003 in CCI sciatic nerve injury- and vincristine-induced neuropathic pain. Two weeks following sciatic nerve injury (A) or continuous vincristine infusion (B), A-740003 was injected 30 minutes (i.p.) before testing. A-740003 demonstrated significant

antiallodynic effects in both neuropathic pain models (A: $F(5;125)=104.19$, $p < 0.0001$; B: $F(5;71)=481.13$, $p < 0.0001$). Circles represent paw withdrawal threshold ipsilateral to the injury. Data represent mean \pm S.E.M. * $p < 0.05$, ** $p < 0.01$ as compared to vehicle-treated animals ($n = 6-12$ per group).

Figure 10. Antinociceptive effects of A-740003 in inflammatory pain models. Two hours following carrageenan injection (A) or two days following CFA injection (B), A-740003 was injected 30 minutes (i.p.) before testing. A-740003 demonstrated significant antihyperalgesic effects in both models (A: $F(7;95)=89.71$, $p < 0.0001$; B: $F(7;83)=23.06$, $p < 0.0001$). Data presented as bar graphs, represent mean \pm S.E.M. for the vehicle group (0 mg/kg, i.p.), the 3 dose-groups (14, 47, 142 mg/kg, i.p.) and the contralateral side (C). ** $p < 0.01$ as compared to vehicle-treated animals ($n = 6-12$ per group). The doses were chosen as part of a testing strategy for project compounds to be compared to each other in $\mu\text{mol/kg}$ doses.
