ABSTRACT

Here, we investigate the effects of renal ischemia/reperfusion (I/R) on the degree of renal injury, dysfunction, and inflammation in interleukin (IL)-6 knockout (IL-6−/−) mice and mice administered a monoclonal antibody against IL-6. IL-6−/− mice were subjected to bilateral renal artery occlusion (30 min) and reperfusion (24 h). At the end of experiments, indicators and markers of renal dysfunction, injury, and inflammation were measured. Kidneys were used for histological evaluation of renal injury. Renal expression of the adhesion molecules intercellular adhesion molecule-1 (ICAM-1) and P-selectin, as well as nitration of proteins in the kidney, were determined using immunohistochemistry. In addition, wild-type mice were pretreated (24 and 1 h before ischemia) with an IL-6 antibody to mimic the effects that would be seen in IL-6−/− mice. IL-6−/− mice and wild-type mice administered the IL-6 antibody demonstrated significantly reduced plasma urea and creatinine levels, indicating reduction of renal dysfunction caused by I/R. Neutrophil infiltration was also significantly reduced in IL-6−/− mice and wild-type mice administered the IL-6 antibody subjected to renal I/R. Proinflammatory cytokines (tumor necrosis factor-α and IL-1β) in renal tissues were significantly attenuated in IL-6−/− mice to levels seen in wild-type mice. IL-6−/− mice demonstrated reduced histological evidence of tubular injury and markedly reduced immunohistochemical evidence of ICAM-1, P-selectin, and nitrotyrosine when subjected to renal I/R. We propose that endogenous IL-6 enhances the degree of renal injury, dysfunction, and inflammation caused by I/R of the kidney by promoting the expression of adhesion molecules and subsequent oxidative and nitrosative stress.

Interleukins mediate intercellular communication that triggers the immunologic responses of alloantigen recognition and defense or tolerance. Although certain cytokines display stimulatory effects in vitro, others appear to attenuate T-cell responsiveness. The impact of these complementary and apparently competitive effects in vivo is still incompletely understood.

Interleukin (IL)-6 is a pleiotropic cytokine, primarily involved in the regulation of immune and inflammatory responses. IL-6 is not only generated by T- and B-lymphocytes, monocytes/macrophages, fibroblasts, vascular smooth muscle cells, and endothelial cells, but also by mesangial and tubular epithelial cells (Fukatsu et al., 1993). IL-6 has many biological properties; for instance, it activates signal transducer and activator of transcription (STAT) 3 transcription factor, stimulates the expression of tissue factor, monocyte chemoattractant protein-1, matrix-degrading enzymes, and low-density lipoprotein receptors in macrophages (Hamanaka et al., 1992; Biswas et al., 1998), causes platelet aggregation, proliferation of vascular smooth muscle cells (Ikeda et al., 1991, 1993), and formation of C-reactive protein and fibrinogen by hepatocytes. It also regulates the expression of adhesion molecules and other cytokines in endothelial cells including IL-1β and tumor necrosis factor (TNF)-α, which in
However, the role of endogenous IL-6 in the tissue injury and inflammation associated with ischemia/reperfusion (I/R) is controversial. Cerebral I/R leads to the rapid expression of IL-6, whereas IL-6 knockout mice subjected to cerebral I/R exhibit reduced survival, suggesting that endogenous IL-6 protects the brain against I/R injury (Herrmann et al., 2003). In contrast, the inflammatory response caused by I/R of the intestine is significantly reduced in IL-6 knockout (IL-6$^{-/-}$) mice, suggesting that an enhanced expression of IL-6 contributes to gut I/R injury (Yokota et al., 2003). In contrast to this, suppression of the I/R-induced expression of IL-6 may mediate the protective effects of HMG-CoA reductase inhibitors in experimental renal I/R injury, suggesting that IL-6 protects the kidney against I/R injury (Yokota et al., 2003). The role of endogenous IL-6 in renal I/R also results in a significant and sustained increase in the expression of the IL-6 gene (Takada et al., 1997), and in cold ischemia, changes in IL-6 mRNA expression are limited to the tubules and do not occur in the glomerulus (Kaminska et al., 2003). Thus, the role of endogenous IL-6 in the renal injury, dysfunction, and inflammation associated with renal ischemia and reperfusion is unclear.

The expression of adhesion molecules such as intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1, and selectins, such as P- and E-selectin (Rabb et al., 1997; Chamoun et al., 2000), followed by the adhesion, activation, and transmigration of polymorphonuclear leukocytes (PMNs) into renal tissues and subsequent production of reactive oxygen species (ROS) and nitric oxide (Rabb et al., 1997), contribute significantly to the development of renal I/R injury and associated ischemic acute renal failure. Furthermore, nitric oxide reacts with superoxide anion to form peroxynitrite, which causes injury via direct oxidant injury and protein tyrosine nitration.

This study was designed to investigate the role of endogenous IL-6 in the tissue injury, dysfunction, and inflammation caused by renal I/R. Specifically, we have investigated the effects of bilateral renal ischemia (30 min) and reperfusion (24 h) on renal injury and dysfunction. To gain a better insight into the mechanism(s) of action of the beneficial effects following the removal of endogenous IL-6 in mice, we have investigated the expression of adhesion molecules (ICAM-1 and P-selectin), activation of neutrophils, levels of lipid peroxidation, and cytokines in IL-6$^{-/-}$ mice and their wild-type litter mates. Following this, we then proceeded to investigate the role of IL-6 in renal I/R using an antibody directed against IL-6. This study provides evidence that endogenous IL-6 contributes to renal I/R injury and inflammation.

**Materials and Methods**

**Animals.** Forty-two male C57BL/6J × 129/SV/EV and 14 male IL-6$^{-/-}$ mice of a mixed genetic background (20–30 g, kindly supplied by Prof. G. Ciliberto, IRBM, Pomezia, Italy) were used to assess the role of IL-6 in the pathogenesis of renal I/R in the mouse. IL-6$^{-/-}$ mice were generated by gene targeting as previously described (Poli et al., 1994). Briefly, embryonic stem cell clones carrying the IL-6 mutation were injected into blastocysts of C57BL/6J and planted into the uteri of C57BL/6J foster mothers. Male chimeras were mated to females, and female offspring heterozygous for the mutation were bred once with mice of the 129/SV/EV strain, the strain from which the embryonic stem cells were derived. The resulting heterozygous offspring were bred together to generate mice homozygous for the IL-6 mutation. IL-6$^{-/-}$ mice have previously been shown to develop a normal glomerular architecture and in particular a normal mesangium (Etñner et al., 1997). Mice were allowed access to food and water ad libitum and were cared for in compliance with Italian regulations on protection of animals used for experimental and other scientific purposes (D.M. 116192), as well as with the European Economic Community regulations (O.J. of E.C. L358/1 12/18/1986).

**Renal Ischemia/Reperfusion.** Mice were anesthetized using chloral hydrate (125 mg/kg i.p.), and core body temperature was maintained at 37°C using a homeothermic blanket. For the first study, mice were divided into the following four groups for experiments involving IL-6$^{-/-}$ mice: I/R wild-type group, wild-type mice that underwent renal ischemia for 30 min followed by reperfusion for 24 h (n = 6); I/R IL-6$^{-/-}$ group, knockout mice that underwent renal ischemia for 30 min followed by reperfusion for 24 h (n = 7); sham wild-type group sham operated, wild-type mice that were subjected to the surgical procedures described below but were not subjected to renal I/R (n = 4); sham IL-6$^{-/-}$ group, knockout mice that were subjected to the surgical procedures described below but were not subjected to renal I/R (n = 4). No evidence of IL-6 has previously been detected in the plasma of this strain of IL-6$^{-/-}$ mice subsequent to I/R (Cuzzocrea et al., 1999).

In a separate study, another set of C57BL/6J mice was divided into four groups for experiments involving the use of a neutralizing rat (monoclonal) anti-mouse IL-6 antibody (IL-6 MAb, 10 μg/day i.p.; BioSource International, Camarillo, CA): I/R control group, wild-type mice that were administered the isotype control (IgG1, 10 μg/day i.p.; BioSource International, Camarillo, CA); I/R control group, wild-type mice that were administered the isotype control (IgG1, 10 μg/day i.p.; BioSource International, Camarillo, CA); I/R control group, wild-type mice that were administered the isotype control (IgG1, 10 μg/day i.p.; BioSource International, Camarillo, CA); I/R control group, wild-type mice that were administered the isotype control (IgG1, 10 μg/day i.p.; BioSource International, Camarillo, CA).
ducibility of renal functional impairment, while minimizing mortality in these animals (Chatterjee et al., 2003). After the renal clamps were removed, the kidneys were observed for a further 5 min to ensure reflow after which 1 ml of saline at 37°C was injected into the abdomen and the incision was sutured in two layers. Mice were then returned to their cages where they were allowed to recover from anesthesia and observed for 24 h. Sham-operated mice underwent identical surgical procedures to I/R mice except that microaneurysm clamps were not applied.

### Measurement of Biochemical Parameters
At the end of the reperfusion period, 1-ml blood samples were collected from anesthetized mice via cardiac puncture. The samples were centrifuged (6000g for 3 min) to separate plasma. All plasma samples were analyzed for biochemical parameters within 24 h after collection or stored at −80°C. Plasma urea and creatinine concentrations were used as indicators of renal function (Chatterjee et al., 2003).

### Histological Evaluation
Kidneys were removed from mice at the end of the experimental period after tying the renal pedicle and cut in a sagittal section into two halves. These tissue samples were fixed by immersion in 10% (w/v) formaldehyde in phosphate-buffered saline (PBS; 0.01 M; pH 7.4) at room temperature for 1 to 3 days. After dehydration using graded ethanol, the tissue was embedded in Paraplast (Sherwood Medical, Mahwah, NJ) and cut in fine (8-μm) sections and mounted on glass slides. Sections were then deparaffinized with xylene, counterstained with hematoxylin and eosin, and viewed under a light microscope (Dialux 22; Leitz, Milan, Italy).

### Polymorphonuclear Leukocyte Influx into Renal Tissues
Because it has become apparent that the myeloperoxidase and naphthal-AS-D-chloracetate esterase assays can crossreact with monocytes and macrophages (Yehesklit et al., 2000), standard hematoxylin-eosin staining was performed to estimate the presence of PMNs, based on the morphology of the nucleus. The total number of infiltrating leukocytes (e.g., neutrophils and mononuclear cells) in cortical interstitial spaces was assessed quantitatively by counting the number of PMNs in 20 high-powered fields.

### Malondialdehyde Measurement
Malondialdehyde (MDA) levels in kidney samples were determined as an indicator of lipid peroxidation, as previously described (Chatterjee et al., 2003). Tissues were homogenized in a 1.15% KCl solution. An aliquot of the homogenate was added to a reaction mixture containing 200 μl of 8.1% SDS, 1500 μl of 20% acetic acid (pH 3.5), 1500 μl of 0.8% thiobarbituric acid, and 700 μl of distilled water. The mixture was then boiled for 1 h at 95°C and centrifuged at 3000g for 10 min. The absorbency of the supernatant was measured by spectrophotometry at 560 nm.

### Immunohistochemical Localization of Nitrotyrosine
Tyrosine nitration was detected in kidney sections by immunohistochemistry as previously described (Chatterjee et al., 2003). Briefly, tissues were fixed in 10% buffered formalin, and 8-μm sections were prepared from paraffin-embedded tissues. After deparaffinization, endogenous peroxidase was quenched with 0.3% H2O2 in 60% methanol for 30 min. The sections were permeabilized with 0.1% Triton X-100 in PBS for 20 min. Nonspecific adsorption was minimized by incubating the sections in 2% (v/v) normal goat serum in PBS for 20 min. Endogenous avidin and biotin binding sites were blocked by sequential incubation for 15 min with avidin and biotin (DBA, Milan, Italy). The sections were then incubated overnight with a 1:1000 dilution of primary anti-nitrotyrosine antibody (DBA) or with control solutions. Controls included buffer alone or nonspecific purified rabbit IgG.

### Immunohistochemical Analysis of ICAM-1 and P-Selectin
Localization of ICAM-1 and P-selectin in kidney sections was determined as previously described (Cockerill et al., 2001). Briefly, sections were incubated overnight at 4°C with primary anti-ICAM-1 (CD54) or anti-P-selectin antibody [1:500 (v/v)] in PBS (DBA). Controls included kidney sections incubated with buffer alone or nonspecific purified IgG (DBA). After blocking endogenous avidin and biotin, specific labeling of antigen-antibody complex was visualized using chromogen diaminobenzidine.

### Measurement of Cytokines
TNF-α and IL-1β levels were evaluated in kidney samples following reperfusion. The assay was carried out by using a colorimetric commercial kit (Calbiochem, San Diego, CA). The enzyme-linked immunosorbent assay has a lower detection limit of 30 pg/ml.

### Materials
Unless otherwise stated, all compounds used in this study were purchased from Sigma-Aldrich (St. Louis, MO). All solutions used in vivo were prepared using nonpyrogenic saline (0.9% (w/v) NaCl; Baxter Healthcare Ltd., Thetford, Norfolk, UK).

### Statistical Analysis
All values described in the text and figures are expressed as mean ± S.E.M. for n observations. Each data point represents biochemical measurements obtained from four to seven separate animals. For histological scoring, each data point represents analysis of kidneys taken from four to seven individual animals. Statistical analysis was carried out using GraphPad Prism/Instat 1.1 (GraphPad Software Inc., San Diego, CA). Data were analyzed using one-way analysis of variance followed by Dunnett’s post hoc test. *P < 0.05 was considered to be significant.

### Results

#### Renal Dysfunction in Wild-Type Mice Treated with an IL-6 MAb and in IL-6−/− Mice: Plasma Urea and Creatinine
When compared with sham-operated mice, I/R caused a significant increase in the plasma levels of urea and creatinine in wild-type (control) mice (Fig. 1, A–D), suggesting a significant degree of renal dysfunction in both studies. The increases in the plasma levels of urea and creatinine seen in IL-6−/− mice subjected to I/R were significantly smaller than those seen in their wild-type litter mates (Fig. 1, A and B), suggesting a marked reduction in the renal dysfunction associated with renal I/R. However, the degree of protection from renal dysfunction observed with the IL-6 MAb in wild-type mice (urea, 41% attenuation; creatinine, 44% attenuation) (Fig. 1, C and D) was not as substantial as that seen in IL-6−/− mice (urea, 58% attenuation; creatinine, 86% attenuation) (Fig. 1, A and B).

#### Renal Injury in Wild-Type Mice Treated with an IL-6 MAb and in IL-6−/− Mice: Histological Assessment
When compared with sham-operated mice (Figs. 2A and 3A), histological examination of kidneys obtained from wild-type (control) mice subjected to I/R demonstrated a significant degree of renal injury (Figs. 2B and 3B). Specifically, kidneys obtained from these animals exhibited degeneration of tubular structure, tubular dilatation, swelling and necrosis, luminal congestion, and eosinophilia. In contrast, renal sections obtained from IL-6−/− mice which underwent I/R demonstrated a marked reduction in the severity of these histological features of renal injury (Fig. 2B) when compared with kidneys obtained from IL-6 wild-type mice subjected to I/R (Fig. 2C). In addition, renal sections obtained from mice treated with 10 μg/day IL-6 MAb that underwent I/R also demonstrated a marked reduction in the severity of the above histological features of renal injury (Fig. 3B), when compared with kidneys obtained from control mice subjected to I/R (Fig. 3C).

#### Renal Inflammation in Wild-Type Mice Treated with an IL-6 MAb and in IL-6−/− Mice: PMN Counts and MDA Levels
Quantitation of infiltrating PMNs into renal tissues showed that there was only a minimal number of PMNs in nonischemic kidneys obtained from sham-operated mice in both studies (Fig. 4, A and B). However, a significant
number of infiltrating PMNs were observed in the renal cortex of mice subjected to I/R of the kidney in both studies (Fig. 4, A and B). The number of PMNs infiltrating into renal tissues of IL-6−/− mice (Fig. 6A) and mice treated with the IL-6 MAb (Fig. 6B) was significantly attenuated by approximately 59 and 50%, respectively. When compared with sham-operated mice, the kidneys obtained from wild-type mice subjected to I/R demonstrated a significant increase in MDA levels (Fig. 5), thus suggesting increased lipid peroxidation in renal tissues. The increase in the tissue level of MDA seen in IL-6−/− mice subjected to I/R was significantly smaller than those seen in their wild-type litter mates (Fig. 5).

Renal Inflammation Caused by I/R in IL-6−/− Mice: Nitrotyrosine Formation. When compared with sham-operated mice (Fig. 6A), immunohistochemical analysis of kidney sections obtained from wild-type mice subjected to I/R demonstrated a positive staining for nitrotyrosine (Fig. 6B). In contrast, renal sections obtained from IL-6−/− mice that underwent I/R demonstrated no positive staining for nitrotyrosine when compared with kidneys obtained from wild-type mice subjected to I/R (Fig. 6C). This suggests reduced nitration of proteins during I/R in mice lacking IL-6.

Renal Inflammation Caused by I/R in IL-6−/− Mice: ICAM-1 and P-Selectin Expression. When compared with kidneys obtained from sham-operated mice (Figs. 7A and 8A), kidneys obtained from wild-type mice demonstrated marked staining for ICAM-1 (Fig. 7B) and P-selectin (Fig. 8B), suggesting adhesion molecule expression during reperfusion. A marked reduction in the staining for both ICAM-1 and P-selectin was observed in kidneys obtained from IL-6−/− mice subjected to renal I/R (Figs. 7C and 8C) when compared with kidneys from their wild-type litter mates. This suggests a reduction in the expression of these adhesion molecules during reperfusion in mice lacking IL-6.

Renal Inflammation Caused by I/R in IL-6−/− Mice: Kidney TNF-α and IL-1β. To determine whether endogenous IL-6 may modulate the inflammatory process through the regulation of the secretion of other cytokines, we analyzed the tissue levels of TNF-α and IL-1β in IL-6−/− mice and their wild-type litter mates. When compared with sham-operated mice, I/R caused a significant increase in the tissue levels of TNF-α and IL-1β in wild-type mice (Fig. 9, A and B). The increases in the tissue levels of TNF-α and IL-1β seen in IL-6−/− mice subjected to I/R were significantly smaller than those seen in their wild-type litter mates (Fig. 9, A and B).

There were no differences in any of the above parameters measured between sham-operated groups (see Figs. 1, 4, 5, and 9).

Discussion

We demonstrate here that the renal injury, dysfunction, and inflammation caused by bilateral occlusion (30 min) and reperfusion (24 h) is significantly smaller in mice in which the gene for IL-6 was deleted (IL-6−/−) mice) than in their wild-type litter mates. Specifically, we found that I/R in wild-type mice caused significant renal dysfunction; characteristic histological signs of marked tubular injury; significant PMN accumulation and lipid peroxidation; increased nitration of proteins; a marked expression/up-regulation of the adhesion molecules, ICAM-1 and P-selectin; and a significant increase in the renal tissue levels of the proinflammatory cytokines, TNF-α and IL-1β. All these data confirmed a well known pattern of renal injury, dysfunction, and inflammation...
caused by I/R of the kidney (Paller, 1994a; Sheridan and Bonventre, 2001). Moreover, our findings are in agreement with the notion that renal I/R causes tubular dysfunction (Paller, 1994b) and secondary inflammation (Dragun et al., 2000). We report here for the first time that all of the above signs of renal injury, dysfunction, and inflammation were significantly reduced in IL-6−/− mice and in wild-type mice in which endogenous IL-6 was blocked. This finding supports the view that endogenous IL-6 enhances the renal injury, dysfunction, and inflammation caused by I/R in mice. Although plasma/kidney levels of IL-6 were not measured in IL-6−/− mice, a previous study using this strain of knockout mouse demonstrated that IL-6 levels were undetectable in the plasma of these mice before or after I/R (Cuzzocrea et al., 1999). Additionally, although mortality was not measured or analyzed statistically in this study, less IL-6−/− mice died during renal I/R than wild-type mice that were subjected to I/R.

There is now good evidence that I/R and/or inflammation leads to a significant increase in the expression of IL-6 in many organs including the brain (Maeda et al., 1994), myocardium (Kukielka et al., 1995), hind limb (Yassin et al., 2002), and gut (Yao et al., 1997). Our conclusion that endogenous IL-6 contributes to tissue injury and inflammation is supported by a number of other studies. In IL-6−/− mice, the induction of acute-phase proteins, weight loss, and hyperglycemia caused by injection of turpentine were dramatically reduced (Alonzi et al., 1998a). The recruitment of PMNs caused by injection of carrageenan into a subcutaneous air

Fig. 2. Renal injury in IL-6−/− mice: histological examination. Renal sections taken from a sham-operated mouse (A), a mouse subjected to renal I/R (B), and an IL-6−/− mouse subjected to renal I/R (C). Hemotoxylin and eosin, original magnification 150×, figures are representative of at least three experiments performed on different days (n = 4–7 for all groups).

Fig. 3. Renal injury in mice treated with an IL-6 MAb: histological examination. Renal sections taken from a sham-operated mouse administered 10 μg/day IgG1 isotype control (A), a mouse subjected to renal I/R administered 10 μg/day IgG1 isotype control (B), and a mouse subjected to renal I/R administered 10 μg/day IL-6 MAb (C). Hemotoxylin and eosin, figures are representative of at least three experiments performed on different days (n = 4–10 for all groups).
pouch was also substantially reduced in IL-6 knockout mice when compared with their wild-type litter mates (Romano et al., 1997). The arthritis (accumulation of PMNs in the knee joint and related tissue damage) caused by collagen was substantially attenuated in IL-6 knockout mice (Alonzi et al., 1998b). Most notably, the tissue injury and inflammation caused by splanchnic artery occlusion and reperfusion is significantly reduced in IL-6 knockout mice (Cuzzocrea et al., 1999). All of the above studies support the hypothesis that endogenous IL-6 enhances the degree of inflammation and tissue injury caused by a number of different stimuli, including I/R.

What then is (are) the mechanism(s) by which endogenous IL-6 amplifies the inflammatory response and ultimately the tissue injury and dysfunction caused by renal ischemia and reperfusion? It is well known that the release of a cascade of...

Fig. 4. Renal inflammation in wild-type mice treated with an IL-6 MAb and in IL-6 knockout mice: PMN infiltration. The total number of infiltrating leukocytes (e.g., neutrophils and mononuclear cells) in cortical interstitial spaces was assessed quantitatively by counting the number of PMNs in 20 high-power fields. PMN counts (A) were measured subsequent to sham operation [Sham WT (wild-type), n = 4; Sham IL-6 knockout, n = 4] or renal I/R [I/R WT, n = 6; I/R IL-6 knockout, n = 7]. PMN counts (B) were measured subsequent to sham operation [Sham IgG1 (10 µg/day), n = 4; Sham IL-6 MAb (10 µg/day), n = 4] or renal I/R [I/R IgG1 (10 µg/day), n = 8; I/R IL-6 MAb (10 µg/day), n = 10]. Data represent mean ± S.E.M. for n observations. * P < 0.05 versus I/R WT or I/R IgG1 group.

Fig. 5. Renal inflammation caused by I/R in IL-6 knockout mice: MDA levels (lipid peroxidation). MDA levels were measured as a marker of lipid peroxidation subsequent to sham operation [Sham WT (wild-type), n = 4; Sham IL-6 knockout, n = 4] or renal I/R [I/R WT, n = 6; I/R IL-6 knockout, n = 7]. Data represent mean ± S.E.M. for n observations. * P < 0.05 versus I/R WT or I/R IgG1 group.

potent inflammatory mediators into the systemic circulation is central to any severe illness. There is evidence that the proinflammatory cytokines TNF-\(\alpha\) and IL-1\(\beta\) help to propagate the extension of a local or systemic inflammatory process (Utsunomiya et al., 1991; Alonzi et al., 1998a), especially during sepsis, and have been used to predict mortality in patients. We confirm here that the inflammatory process caused by renal I/R leads to a substantial increase in the levels of both TNF-\(\alpha\) and IL-1\(\beta\) in the kidney. Interestingly, the levels of these two proinflammatory cytokines were significantly lower in kidneys obtained from animals that are unable to produce endogenous IL-6 (IL-6\(^{-/-}\) mice). This finding suggests that in the presence of endogenous IL-6, the degree of inflammation, and, hence, the formation of TNF-\(\alpha\) and IL-1\(\beta\), caused by renal I/R are significantly enhanced. In addition, Simmons et al. (2004) have recently reported that IL-6 and IL-8 are significant predictors of mortality in end-stage renal disease patients (Simmons et al., 2004), and this is supported by previous studies demonstrating that IL-6 and mortality are highly associated in patients with chronic kidney disease (Bologa et al., 1998; Pecoits-Filho et al., 2002). It would appear that there were no compensatory mechanisms for IL-6 depletion in these mice; however, it is possible that gp130 gene expression may have been higher in these mice. Further investigation of this possibility is warranted.

There is evidence that renal I/R leads to an increase in the expression of P-selectin and ICAM-1 in rat (Dragun et al., 2000) and man (Koo et al., 1998) and, hence, an excessive accumulation of PMNs within the kidney. IL-6 enhances PMN accumulation within the renal tissue by causing amplification (positive feedback) of the formation of the proinflammatory cytokines TNF-\(\alpha\) and IL-1\(\beta\) (see above) and/or of the expression of the adhesion molecules ICAM-1 and P-
selectin. We document here that the degree of staining for ICAM-1 and P-selectin was significantly reduced in IL-6−/− mice suggesting that endogenous IL-6 enhances the expression of ICAM-1 and P-selectin. It is possible that the reduced expression of TNF-α and IL-1β observed in IL-6−/− mice subjected to renal I/R may contribute to the reduced expression of ICAM-1 and P-selectin in these animals. It should, however, also be noted that the expression of ICAM-1 caused by renal I/R is not abolished in mice lacking TNF-receptor-1 and IL-1-receptor-1, suggesting that TNF-α and IL-1β are not essential for the expression of ICAM-1 in the kidney (Burne-Taney et al., 2001).

STAT3 is the main mediator of IL-6 cytokine signaling; it modulates cellular responses to IL-6 and mediates IL-10 function in macrophages (Maritano et al., 2004). STAT3 has been implicated in conditions of inflammation, and IL-6 has been shown to activate STAT3 during both ischemia and reperfusion (Hierholzer et al., 1998). IL-6-related cytokines have now been demonstrated as the main activators of STAT3. In a recent study, STAT3 activation was reduced in IL-6−/− mice subjected to colitis (Suzuki et al., 2001) and that endogenous IL-6 exacerbates the degree of renal injury, dysfunction, and inflammation caused by I/R injury. This finding indicates that IL-6 can act as a proinflammatory cytokine in renal disorders associated with I/R and that strategies aimed at reducing the formation and/or the effects of IL-6 may be useful in conditions associated with renal ischemia and inflammation.

In conclusion, this study demonstrates for the first time that endogenous IL-6 exacerbates the degree of renal injury, and that strategies aimed at reducing the formation and/or the effects of IL-6 may be useful in conditions associated with renal ischemia and inflammation.

Acknowledgment
We thank Professor Gennaro Ciliberto (IRBM, Pomezia, Latina, Italy) for the generous supply of wild-type and IL-6−/− mice.
