ABSTRACT

This study first investigates the anticancer effect of plumbagin (5-hydroxy-2-methyl-1,4-naphthoquinone) in human nonsmall cell lung cancer cells, A549. Plumbagin has exhibited effective cell growth inhibition by inducing cancer cells to undergo G2/M phase arrest and apoptosis. Blockade of cell cycle was associated with increased levels of p21 and reduced amounts of cyclinB1, Cdc2, and Cdc25C. Plumbagin treatment also enhanced the levels of inactivated phosphorylated Cdc2 and Cdc25C. Blockade of p53 activity by dominant-negative p53 transfection partially decreased plumbagin-induced apoptosis and G2/M arrest, suggesting it might be operated by p53-dependent and independent pathway. Plumbagin treatment triggered the mitochondrial apoptotic pathway indicated by a change in Bax/Bcl-2 ratios, resulting in mitochondrial membrane potential loss, cytochrome c release, and caspase-9 activation. We also found that c-Jun NH2-terminal kinase (JNK) is a critical mediator in plumbagin-induced cell growth inhibition. Activation of JNK by plumbagin phosphorylated p53 at serine 15, resulting in increased stability of p53 by decreasing p53 and MDM2 interaction. SP600125 (anthra [1,9-cd]pyrazol-6(2H)-one-1,9-pyrazoloanthrone), a specific inhibitor of JNK, significantly decreased apoptosis by inhibiting the phosphorylation of p53 (serine 15) and subsequently increased the interaction of p53 and MDM2. SP6000125 also inhibited the phosphorylation of Bcl-2 (Ser70) induced by plumbagin. Further investigation revealed that plumbagin’s inhibition of cell growth effect was also evident in a nude mice model. Taken together, these results suggest a critical role for JNK and p53 in plumbagin-induced G2/M arrest and apoptosis of human nonsmall cell lung cancer cells.

Lung cancer is one of the leading causes of death in the world, and nonsmall cell lung carcinoma accounts for approximately 75 to 85% of all lung cancers (Raez and Lilienbaum, 2004). Nonsmall cell lung cancers commonly develop resistance to radiation and chemotherapy and often present at stages too late for surgical intervention. Since current treatment modalities are inadequate, novel therapies are needed to reduce the effects of the increasing incidence in pulmonary neoplasm (Raez and Lilienbaum, 2004; Kelly, 2005).

The tumor suppressor protein p53 is targeted by a wide variety of intracellular and extracellular stimuli, such as withdrawal of growth factors, hypoxia, irradiation, chemicals, and defects in nucleotide synthesis (Harris and Levine, 2005). The activation of p53 leads, primarily through its transcriptional function, to either apoptosis, eliminating those cells harboring severely damaged DNA, or growth arrest, allowing damaged DNA to be repaired and thereby suppressing tumor formation (Harris Robles et al., 2002; Levine, 2005). Stability and activity of p53 are believed to be regulated in part by posttranslational modifications, such as phosphorylation and acetylation. Phosphorylation on NH2-terminal residues, especially Ser15, Thr18, Ser20, and Ser37, is believed to affect interaction with the negative regulator p53 and Mdm2. Therefore, p53 is a critical mediator in plumbagin-induced cell growth inhibition and apoptosis.

ABBREVIATIONS: JNK, c-Jun NH2-terminal kinase; plumbagin, 5-hydroxy-2-methyl-1,4-naphthoquinone; DMSO, dimethyl sulfoxide; PI, propidium iodide; PI, propidium iodide; SP600125, anthra [1,9-cd]pyrazol-6(2H)-one-1,9-pyrazoloanthrone; phospho-JNK, phosphorylated c-Jun NH2-terminal kinase; XTT, sodium 3-[1-(phenylamino-carbonyl)-3,4-tetrazolium]-bis(4-methoxy-6-nitro)benzene-sulfonic acid hydrate; TUNEL, terminal deoxynucleotidyl transferase dUTP nick-end labeling; CHAPS, 3-[3-cholamidopropyl]dimethylammonio]-1-propanesulfonic acid; JC-1, 5,5’,6,6’-tetrachloro-1,1’,3,3’-tetraethylbenzimidazolylcarbocyanine iodide; G418, geneticin; PARP, poly(ADP-ribose) polymerase.

484
Plumbago zeylanica rupts the binding motif of Bcl-2 and makes it unable to addition, phosphorylation of prosurvival Bcl-2 by JNK dis-totic activity (Liu and Lin, 2005; Yoshida et al., 2005). In indicated that phosphorylation by JNK enhances proapop-tal., 2005; Zu et al., 2005). Several proapoptotic factors have mitochondrial caspase-9 pathway (Chen et al., 2003; Gao et al., 1998; and Lin, 2005). Activated JNK phosphorylates and stabilizes MDM2 and hence contribute to the stabilization of p53. Phosphorylation on COOH-terminal Ser315 and Ser392 in particular is believed to enhance the specific DNA binding of p53 in vitro (Xu, 2003; Bode and Dong, 2004).

c-Jun NH2-terminal kinase (JNK), a member of the mito-gen-activated protein kinase family protein kinases, is an important member of the signal transduction pathway that transduces extracellular signals in intracellular responses and has been implicated in a wide array of physiological processes, including cell growth, differentiation, and apopto-sis (Liu and Lin, 2005). JNK can induce apoptosis in response to a variety of stresses. The proposed mechanisms of this effect are the change of gene expression as well as eliciting its phosphorylation activity to several specific substrates (Liu and Lin, 2005). Activated JNK phosphorylates and stabilizes p53 by abrogating MDM2 association (Fuchs et al., 1998; Buschmann et al., 2000). Recent studies have shown that JNK activation is required for stress-induced release of mi-tochondrial cytochrome c and for apoptosis mediated by the mitochondrial caspase-9 pathway (Chen et al., 2003; Gao et al., 2005; Zu et al., 2005). Several proapoptotic factors have indicated that phosphorylation by JNK enhances proapoptotic activity (Liu and Lin, 2005; Yoshida et al., 2005). In addition, phosphorylation of prosurvival Bel-2 by JNK dis-rupts the binding motif of Bel-2 and makes it unable to antagonize Bax (Zu et al., 2005).

Plumbagin, a quinoid constituent isolated from the root of Plumbago zeylanica L., has been shown to exert antcarci-nogenic, antiatherosclerotic, and antimicrobial effects (Mossa et al., 2004; Srinivas et al., 2004; Ding et al., 2005; Hsieh et al., 2005). It exhibits an inhibitory effect on carci-nogenesis in the intestines, causes cytogenetic and cell cycle changes in mouse Ehrlich ascites carcinoma, and possesses antiproliferation activity in human cervical cancer cells (Singh and Udupa, 1997; Sugie et al., 1998; Srinivas et al., 2004). In this study, we determined the cell growth inhibition activity of plumbagin by using in vitro and in vivo experimental models and examined its effect on cell cycle distribution and apoptosis in human nonsmall cell lung cancer cell A549. Furthermore, to establish plumbagin’s anticancer mechanism, we assayed the levels of cell cycle control- and apoptosis-related molecules, which are strongly associated with the programmed cell death signal transduction pathway and affect the chemosensitivity of tumor cells to anticancer agents.

Materials and Methods

Reagents. Fetal calf serum and RPMI 1640 were obtained from Gibco BRL (Gaithersburg, MD). Plumbagin, dimethyl sulfoxide (DMSO), RNase, and propidium iodide (PI) were purchased from Sigma Chemical Co. (St. Louis, MO). JNK inhibitor SP600125 and Bel-Xs antibody were purchased from Calbiochem (Cambridge, MA). The antibodies to β-actin, cyclinB1, Cdc2, Cdc25C, p21, Bax, Bak, Bel-2, phospho-Bcl-2, and Bel-Xl were obtained from Santa Cruz Biotechnology (Santa Cruz, CA). The antibodies to p53, phospho-p53, MDM2, JNK, phospho-JNK, phospho-Cdc2, phospho-Cdc25C, and cytochrome c were obtained from Cell Signaling Technology (Bever-ly, MA). The pCMV and pCMV-p53mt135 plasmids were supplied by CLONTECH (Palo Alto, CA). Lipofectamine 2000 reagent was obtained from Life Technologies, Inc. (Rockville, MD). COS cells plus UV irradiation cell extract was obtained from Laprice (Brussels, Belgium). MCF-7 cells plus UV irradiation cell extract was obtained from Active Motif (Carlsbad, CA).

Cell Culture. A549 (American Type Culture Collection CCL185; American Type Culture Collection, Manassas, VA) was maintained in RPMI 1640 supplemented with 10% FBS, 10 U/ml penicillin, 10 μg/ml streptomycin, and 0.25 μg/ml amphotericin B. IMR-90 (American Type Culture Collection CCL-186) fibroblast cells were cultured in minimum essential medium (Eagle) with Earle’s balanced salt solution, 2 mM l-glutamine, 1.5 mg/ml sodium bicarbonate, 0.1 mM nonessential amino acids, 1.0 mM sodium pyruvate, 10 U/ml pen-cillin, 10 μg/ml streptomycin, 0.25 μg/ml amphotericin B, and 10% fetal calf serum. Both cell lines were cultured in monolayer culture at 37°C and 5% CO2.

Cell Proliferation and Clonogenic Assay. Inhibition of cell proliferation by plumbagin was measured by sodium 3’-[1-phe-nylaminocar-bonyl]-3,4-tetrazolium]-bis(4-methoxy-6-nitrobenzene-sulfonic acid hydrate (XTT) assay. In brief, cells were plated in 96-well culture plates (1 × 103 cells/well). After 24-h incubation, the cells were treated with plumbagin (0, 2.5, 5, 10, and 20 μM) for 6, 12, 24, and 48 h. An amount of 50 μl of XTT test solution, which was prepared by mixing 5 ml of XTT-labeling reagent with 100 μl of electron coupling reagent, was then added to each well. After 4 h of incubation, the absorbance was measured on an enzyme-linked immunoassorbent assay reader (Multiskan EX; Thermo Electron, Waltham, MA) at a test wavelength of 492 nm and a reference wavelength of 690 nm.

To determine the long-term effects, cells were treated with plumbagin at various concentrations for 1 h. After being rinsed with fresh medium, cells were allowed to grow for 14 days to form colonies that were then stained with crystal violet (0.4 g/l; Sigma). Clonogenic assay was used to elucidate the possible differences in long-term effects of plumbagin in A549 and IMR-90 cells.

Cell Cycle Analysis. To determine cell cycle distribution analysis, 5 × 105 cells were plated in 60-mm dishes and treated with plumbagin (0, 10, and 20 μM) for 6 h. After treatment, the cells were collected by trypsinization, fixed in 70% ethanol, washed in phosphate-buffered saline, resuspended in 1 ml of phosphate-buffered saline containing 1 mg/ml RNase and 50 μg/ml PI, incubated in the dark for 30 min at room temperature, and analyzed by EPICS flow cytometer. The data were analyzed using Multicycle software (Phoe-nix Flow Systems, San Diego, CA).

Apoptosis Assay. Cells (1 × 106) were treated with vehicle alone (0.1% DMSO) and various concentrations of plumbagin for indicated times and then collected by centrifugation. Pellets were lysed by DNA lysis buffer (10 mM Tris, pH 7.5, 400 mM EDTA, and 1% Triton X-100) and then centrifuged. The supernatant obtained was incubated overnight with proteinase K (0.1 mg/ml), then with RNase (0.2 mg/ml) for 2 h at 37°C. After extraction with phenol/chloroform (1:1), the DNA was separated in 2% agarose gel and visualized by UV after staining with ethidium bromide.

Quantitative assessment of apoptotic cells was assessed by the terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) method, which examines DNA strand breaks during apoptosis by using BD ApoAlert DNA Fragmentation Assay Kit. In brief, cells were incubated with 0, 10, and 20 μM plumbagin for the indicated times. The cells were trypsinized, fixed with 4% paraformaldehyde, and permeabilized with 0.1% Triton X-100 in 0.1% so-dium citrate. After being washed, the cells were incubated with the reaction mixture for 60 min at 37°C. The stained cells were then analyzed with an EPICS flow cytometer and a fluorescence micro scope at 20× magnification.

Assay for Caspase-9 Activity. The assay is based on the ability of the active enzyme to cleave the chromophore from the enzyme substrate of caspase-9, LEHD-pNA (Ac-Leu-Glu-His-Asp-pNA). Cell lysates were incubated with peptide substrate in assay buffer (100 mM NaCl, 50 mM HEPES, 10 mM dithiothreitol, 1 mM EDTA, 10% glycerol, and 0.1% CHAPS, pH 7.4) for 2 h at 37°C. The release of p-nitroaniline was monitored at 405 nm. Results are represented as the percentage of change in activity compared with the untreated control.
Mitochondrial Membrane Potential Assay. We used mitochondria-specific cationic dye JC-1 (Invitrogen, Carlsbad, CA), which undergoes potential-dependent accumulation in the mitochondria. It is a monomer when the membrane potential (Δψ) is lower than 120 mV and emits a green light (540 nm) following excitation by blue light (490 nm). At higher membrane potentials, JC-1 monomers convert to J-aggregates that emit a red light (590 nm) following excitation by green light (540 nm). Cells were seeded in a 96-well plate. Following treatment with various concentrations of plumbagin for 8 and 12 h, cells were stained with 25 μM JC-1 for 30 min at 37°C. Fluorescence was monitored with the fluorescence plate reader at wavelengths of 490 nm (excitation)/540 nm (emission) and 540 nm (excitation)/590 nm (emission) pairs. Changes in the ratio between the measurement at test wavelengths of 590 nm (red) and 540 nm (green) fluorescence intensities are indicative of changes in the mitochondrial membrane potential (Martin and Forkert, 2004).

Immunoprecipitation/Immunoblot and JNK Activity Assays. Cells were treated with 20 μM plumbagin in the absence or presence of JNK inhibitors for specified intervals of time. Mitochondrial and cytoplasmic fractions were separated using Cytochrome c Releasing Apoptosis Assay Kit (BioVision, Mountain View, CA). For immunoblotting, the cells were lysed on ice for 40 min in a solution containing 50 mM Tris, 1% Triton X-100, 0.1% SDS, 150 mM NaCl, 2 mM Na3VO4, 2 mM EGTA, 12 mM β-glycerophosphate, 10 mM NaF, 16 μg/ml benzamide hydrochloride, 10 μg/ml phenanthroline, 10 μg/ml aprotinin, 10 μg/ml leupeptin, 10 μg/ml pepstatin, and 1 mM phenylmethylsulfonyl fluoride. The cell lysate was centrifuged at 14,000 g for 15 min, and the supernatant fraction was collected for immunoblotting. Equivalent amounts of protein were resolved by SDS-polyacrylamide gel electrophoresis (10–12%) and transferred to polyvinylidene difluoride membranes. After blocking for 1 h in 5% nonfat dry milk in Tris-buffered saline, the membrane was incubated with the desired primary antibody for 1 to 16 h. The membrane was then treated with appropriate peroxidase-conjugated secondary antibody, and the immunoreactive proteins were detected using an enhanced chemiluminescence kit (GE Healthcare, Little Chalfont, Buckinghamshire, UK) according to the manufacturer’s instructions.

For association of p53 and MDM2, cell lysates (300 μg) were incubated with 10 μl of anti-MDM2 for 1 h at 4°C. Immunocomplexes were resolved by 7.5% SDS-polyacrylamide gel electrophoresis. Association of MDM2 with p53 was detected by incubating the blots with anti-MDM2 and anti-p53 antibodies as described above. The JNK mitogen-activated protein kinase activity were determined using kits from Cell Signaling Technology according to the manufacturer’s instructions.

Stable Transfection. Transfection of A549 cells was carried out using Lipofectamine 2000 reagent (Life Technologies). A549 cells were exposed to the mixture of Lipofectamine 2000 reagent and pCMV-p53-mt135 plasmid or empty vector for 6 h. After transfection, cells resistant to neomycin were selected by incubating with medium containing 1 mg/ml G418 (Life Technologies). Individual A549 clones were isolated and tested for constitutive p53 expression. The p53-positive A549 cells were selected and maintained in the presence of G418 (400 μg/ml), as were p53-negative control cells (Xu et al., 2003).

In Vivo Tumor Xenograft Study. Male nude mice [6 weeks old; BALB/c-Agnu (nu/nu)] were purchased from the National Science Council Animal Center (Taipei, Taiwan) and maintained in pathogen-free conditions. A549 cells were injected s.c. into the flanks of nude mice (5 × 106 cells in 200 μl). Tumors were allowed to develop for ~20 days until they reached ~75 mm3, when treatment was initiated. Thirty mice were randomly divided into two groups. The mice in the plumbagin-treated group were i.p. injected with plumbagin in 25% polyethylene glycol (2 mg/kg body weight) in a 0.2-ml volume. The control group was treated with an equal volume of vehicle. After transplantation, tumor size was measured using calipers, and tumor volume was estimated according to the formula: tumor volume (millimeters cubed) = L × W2/2, where L is the length, and W is the width.

Analysis of apoptotic cells in formalin-fixed specimens was by BD ApoAlert DNA Fragmentation Assay Kit as described above. The apoptotic cells were detected using a fluorescent microscope at 20× magnification.

Statistical Analysis. Data were expressed as means ± S.D. Statistical comparisons of the results were made using analysis of variance. Significant differences (p < 0.05) between the means of control and plumbagin-treated cells were analyzed by Dunnett’s test.

Results

Plumbagin Inhibits Cell Proliferation and Clonogenic Survival in A549 Cells. To investigate the potential cell proliferative inhibition activity of plumbagin in lung cancer, we first examined the effect of plumbagin on cell proliferation and clonogenic survival in A549 cells. As shown in Fig. 1A, plumbagin inhibited cell proliferation in A549 cancer cell lines in a concentration- and time-dependent manner. Maximal proliferation inhibition was observed at 48 h with 20 μM plumbagin, which inhibited proliferation in 81.98% of A549 cells and had an IC50 value of 11.69 μM.

We performed in vitro clonogenic assays to determine the antitumor activities of plumbagin inhibition. The in vitro clonogenic assays correlate very well with in vivo assays of tumorigenicity in nude mice (Freedman and Shin, 1974; Shin et al., 1975). Figure 1, B and C, shows the effects of plumbagin on the relative clonogenicity of the control and plumbagin-treated A549 cells. Clonogenicity of A549 cells was reduced in a dose-dependent manner after exposure to plumbagin.

To examine the selection of plumbagin-mediated cell proliferation inhibition, we also evaluated the effect of plumbagin in the normal lung cell line, IMR-90. The results showed that treatment of IMR-90 cells with plumbagin failed to affect the cell proliferation at any of the examined time points (Fig. 1D). In addition, plumbagin also failed to affect the colony formation in IMR-90 cells (Fig. 1, E and F). This result demonstrated that plumbagin possessed selectivity between normal and cancer cells.

Plumbagin Induces Cell Cycle Arrest and Apoptosis in A549 Cells. To examine the mechanism responsible for plumbagin-mediated cell proliferation inhibition, cell cycle distribution was evaluated using flow cytometric analysis. The results showed that treating cells with plumbagin caused a significant inhibition of cell cycle progression in A549 cells at 6 h (Fig. 2A), resulting in a clear increase of the percentage of cells in the G2/M phase compared with the control.

We next assessed the effect of plumbagin on the induction of apoptosis in A549 cells by DNA fragmentation assay. The results showed that plumbagin treatment results in the formation of DNA fragments in A549 cells, as determined by agarose gel electrophoresis in a dose-dependent manner at 48 h and a time-dependent manner at a concentration of 20 μM (Fig. 2, B and C). A quantitative evaluation was also made using TUNEL to detect DNA strand breaks. Compared with vehicle-treated cells, 20 μM plumbagin induced 32.9 and 39% of apoptotic cells in A549 cells at 24 and 48 h, respectively (Fig. 2D). TUNEL-positive cells were also visible using a fluorescence microscope (Fig. 2E). Apoptosis was also evident upon examination of common molecular markers of apoptosis, including the cleavage of the caspase substrate PARP into the 89-kDa cleavage product and caspase-3 acti-
vation. Plumbagin treatment induced both of these markers, which was consistent with the results of DNA fragmentation analysis (Fig. 2F).

To examine the selection of plumbagin-mediated G2/M phase arrest and apoptosis, we also evaluated the effects of plumbagin in IMR-90. The results showed that treatment of IMR-90 cells with plumbagin failed to affect the distribution of cell cycle in IMR-90 cells after 6 h of treatment (Fig. 2G). In addition, plumbagin also failed to induce apoptosis in IMR-90 cells after 24 and 48 h of treatment (Fig. 2H). This result demonstrated that plumbagin possessed selectivity between normal and cancer cells.

**Plumbagin Increases the Expression of p53 and Phosphorylated p53 (Ser15 and Ser392) and Regulates the Levels of Cell Cycle-Related Molecules in A549 Cells.** Because our studies have shown that plumbagin treatment of A549 cells results in G2/M phase cell cycle arrest, we examined the effect of plumbagin on cell cycle-regulatory molecules, including p53, p21, cyclinB1, Cdc25C, and Cdc2. We first assessed the status of p53 in plumbagin-treated A549 cells. Exposure of cells to 20 μM plumbagin enhanced the phosphorylation of p53 on Ser15 and Ser392 (Fig. 3A) without any phosphorylation on serine residues 6, 9, 20, and 46. Plumbagin treatment was also associated with an increase in cells' levels of both p53 and its downstream target, p21 (Fig. 3A). In addition, the association of p53 and MDM2 decreased in a time-dependent manner in plumbagin-treated A549 cells, as detected by immunoprecipitation assay (Fig. 3B).

Next, we assessed the effects of plumbagin on cell cycle-related regulating factor. Plumbagin treatment of the cells resulted in a time-dependent decrease in the protein expres-
tion of cyclinB1, Cdc2, and Cdc25C in A549 cells (Fig. 3C). In addition, exposure of cells to plumbagin for 3 h resulted in an increase in the levels of inactive phospho-Cdc2 (Tyr15) and phospho-Cdc25C (Ser216). Results from time-dependent studies have indicated that decreasing functional Cdc25C by increasing phosphorylation was followed by an increase in phospho-Cdc2 (Fig. 3C). We suggest that Cdc2 action was inhibited by a decrease in Cdc25C expression.

**Plumbagin Induces the Execution of Apoptosis through Activation of the Mitochondrial Pathway.** To investigate the mitochondrial apoptotic events involved in plumbagin-induced apoptosis, we first analyzed the changes in the levels of proapoptotic proteins Bax, Bak, and Bcl-X, and antiapoptotic proteins Bcl-2 and Bcl-X. Western blot analysis showed that treatment of A549 cells with plumbagin increased Bax, Bak, and Bcl-X protein levels (Fig. 3A). In contrast, plumbagin decreased Bcl-2 and Bcl-X protein levels, which led to an increase in the proapoptotic/antiapoptotic Bcl-2 ratio (Fig. 4A). In addition, plumbagin also increased phosphorylation of Bcl-2 (Ser70) in A549 cells.

Both mitochondrial depolarization and the loss of cytochrome c from the mitochondrial intermembrane space have been proposed as the early events during apoptotic cell death. Therefore, we measured mitochondrial membrane potential...
using the mitochondria-specific dye JC-1. We investigated mitochondrial dysfunction by measuring ΔΨm in plumbagin-treated A549 cells at 8 and 12 h (Fig. 4B). Cytosolic extracts were prepared under conditions to preserve the mitochondria, and cytosolic cytochrome c protein levels were measured by immunoblotting analysis. Figure 4C shows that the cytosolic fraction from untreated A549 cells contained no detectable amounts of cytochrome c, whereas it did become detectable after 48 h of 20 μM plumbagin treatment in A549 cells (Fig. 4C).

Hallmarks of the apoptotic process include the activation of cysteine proteases, which represent both initiators and executors of cell death. Upstream caspase-9 activities increased significantly, as shown by the observation that treatment with plumbagin increased caspase-9 activity in A549 cells. This is consistent with the release of cytochrome c into the cytosol (Fig. 4D).

**Plumbagin Induces the Activation of JNK.** Figure 5A shows that activation (phosphorylation) of JNK was evident as early as 1 h after plumbagin treatment and persisted for the duration of the experiment. On the other hand, the expression of JNK (unphosphorylated form) was not altered by plumbagin treatment. Plumbagin-mediated activation of JNK was additionally confirmed by determining phosphorylation of one of its substrates, c-jun. As shown in Fig. 5B, in comparison with the control, the Ser63 phosphorylation of c-jun increased after A549 cells were exposed for 1 h to 20 μM plumbagin. Phosphorylation of c-jun increased relative to the control at all four time points (Fig. 5B).
The Role of p53 in Plumbagin-Mediated Cell Cycle Arrest and Apoptosis. To further define the role of p53 in plumbagin-induced cell cycle arrest and apoptosis, we transfected pCMV-p53mt135 plasmid containing the gene encoding a dominant-negative mutation of p53 that blocks normal p53 activity (Hsu et al., 2005). Overexpression of mutant p53 protein in cells transfected with the dominant-negative p53 mutant plasmid was verified by Western blot using antibody against human p53 (recognizing both wild- and mutant-type p53) (Fig. 6A). Cells expressing p53 mutant were subsequently used to document plumbagin-mediated cell cycle arrest and apoptosis. As shown in Fig. 6B, the inhibition of p53 activity was accompanied by a reduction in the sensitivity of A549 cells to plumbagin-mediated G2/M arrest. The expression of p21 was also inhibited in pCMV-p53mt-transfected A549 cells (Fig. 6C). Furthermore, compared with vehicle-treated cells, induction of apoptosis induced by 20 μM plumbagin decreased from 36.5% in A549 cells to 13.4% in p53 mutant cells after a 24-h treatment (Fig. 6D). However, the inhibition of p53 did not completely abrogate plumbagin-mediated cell cycle arrest and apoptotic death, suggesting that plumbagin-mediated cell cycle arrest and apoptosis is carried through both p53-dependent and -independent manners.

Decrease of Plumbagin-Induced Cell Cycle Arrest and Apoptosis by JNK Chemical Inhibitors. To verify the possible role of JNK in plumbagin-induced apoptosis, A549 cells were pretreated for 1 h with the specific inhibitor for JNK, SP600125. Subsequently, the inhibitor-treated cells were exposed to plumbagin, and then cell cycle distribution and apoptosis were determined. As shown in Fig. 7A, the plumbagin-mediated JNK activation was effectively inhibited by 20 μM SP600125. Flow cytometric analysis of A549 cells exposed to plumbagin for 6 h showed that SP600125 partially blocked plumbagin-mediated G2/M progression (Fig. 7B). Figure 7C shows the effect of JNK inhibitor almost completely abrogating plumbagin-induced apoptosis in A549 cells and mutant p53-transfected A549 cells were treated with 20 μM plumbagin for 6 (cell cycle assay) and 24 h (apoptosis assay). The induction of apoptosis was determined by PI stain and TUNEL analysis. Each value is the mean ± S.D. of three determinations. *, significant difference between control and plumbagin-treated cells, as analyzed by Dunnett’s test (p < 0.05).
cells. In comparison with control cells, the percentage of apoptotic cells was significantly higher in cultures exposed to 20 μM plumbagin, but this effect was blocked by the JNK inhibitor at 24 h (Fig. 7C).

The Role of JNK on p53 and Bcl-2 Phosphorylation. Previous studies have indicated that p53 phosphorylation at Ser15 is a critical event for stabilizing the function of p53. Phosphorylation at this site in vivo was shown to be inhibited by JNK-specific inhibitors, suggesting that JNK may target this serine directly or indirectly (Milne et al., 1995; Fuchs et al., 1998). As shown in Fig. 8A, pretreatment of cells with SP600125 decreased the plumbagin induction of p53 protein and phosphorylation at Ser15. Moreover, a major factor that influences the stability of p53 protein is the binding of p53 with MDM2, and this interaction is inhibited when p53 phosphorylation occurred. As shown in Fig. 8B, the binding of MDM2 to p53 dramatically decreased in plumbagin-treated cells. These data suggest that plumbagin induces p53 phosphorylation through JNK signaling, which stabilizes p53 protein to induce p21 expression.

On the other hand, we tested the involvement of the mitochondrial apoptotic pathway by examining the effect of JNK inhibitors on phospho-Bcl-2 expression. As shown in Fig. 8A, cotreatment of A549 cells with plumbagin and SP600125 completely blocked plumbagin-mediated Bcl-2 phosphorylation at Ser70.

Plumbagin Inhibits Tumor Growth in Nude Mice. To determine whether plumbagin inhibits tumor growth in vivo, equal numbers of A549 cells were injected s.c. into both flanks of the nude mice. Tumor growth inhibition was most evident in mice treated with plumbagin at 2 mg/kg/day, where ~80% reductions in tumor size were observed, in contrast with mice treated with the vehicle (Fig. 9, A and B). No sign of toxicity, as judged by parallel monitoring body weight, was observed in plumbagin-treated mice.

To gain insight into the mechanism of plumbagin's inhibition of tumor growth in vivo, we harvested the A549 tumor xenografts from vehicle- and plumbagin-treated mice after treatments and assessed apoptosis by TUNEL analysis. We also extracted proteins to assess for levels of phospho-p53, phospho-JNK, cleaved PARP, and activated caspase-3 proteins. As shown in Fig. 9C, increase of TUNEL-positive cells were observed in tumors of the plumbagin-treated mice, compared with tumors of vehicle-treated mice. In addition, the PARP cleavage, caspase-3 activation, phospho-p53 (Ser15), and phospho-JNK levels increased in the tumors from the...
Lung cancer is the most common neoplasm in human in both developed and developing countries (Raez and Lilenbaum, 2004). In our study, we have found that plumbagin effectively inhibits tumor cell growth in vitro, concomitant with induction of cell cycle arrest and apoptosis, and inhibits tumor cell growth in nude mice. Furthermore, because plumbagin does not exhibit any significant toxicity on normal lung cancer, this suggests that plumbagin possesses selectivity between normal and cancer cells.

Tumor suppressor gene p53 is a key element in the induction of cell cycle arrest and apoptosis following DNA damage or cellular stress in human cells (Harris and Levine, 2005). Cell cycle arrest that is dependent on p53 requires transactivation of p21 or other cell cycle-related factors (Taylor and Stark, 2001). The induction of p21 causes subsequent arrest in the G1/G0 or G2/M phase of the cell cycle by binding of the cyclin-cdk complex (Taylor and Stark, 2001; Coqueret, 2003).

In this study, we have shown that treatment of A549 cells with plumbagin resulted in the accumulation of p53 and phospho-p53 (Ser15 and 392) both in vivo and in vitro. Indeed, we also have found that plumbagin increases the expression of p21 and arrests the cell cycle at G2/M. The up-regulation of p21 by plumbagin was inhibited by suppression of normal p53 activity via dominant-negative p53, suggesting that p21 is regulated in a p53-dependent manner. In addition, treatment of A549 with plumbagin also decreases the expression of cyclinB1, Cdc25C, and Cdc2, whereas it increases the phosphorylation of Cdc2 and phospho-Cdc25C. Therefore, we suggest that plumbagin may prove to be a valuable tool for inhibition of Cdc2/cyclinB1 in lung cancers for the following reasons: the down-regulation of cyclinB1 by plumbagin; the induction of p21 by plumbagin in a p53-dependent manner, which may subsequently inhibit the function of Cdc2 by forming Cdc2/p21 complex; and the increase of phospho-Cdc25C followed by an increase in inactivated phospho-Cdc2, suggesting that increased phospho-Cdc25C levels may also decrease functioning phosphatase for dephosphorylating and activating Cdc2.

Increased expression of p21 is associated with cell cycle inhibition, differentiation, and cellular senescence (Chen et al., 2002). In addition, p21 can bind to proliferating cell nuclear antigen, thereby blocking DNA synthesis (Gartel and Radhakrishnan, 2005). Jaiswal et al. (2002) have indicated that plumbagin treatment caused an increase of p21 expression and a decrease of DNA repair resulting in cell death in mouse embryonic fibroblast cells. However, p21 has also been reported to influence the outcome of the p53 response to DNA damage and play a protective role on survival signal against apoptosis (Seoane et al., 2002; Kuo et al., 2004). The up-regulation of p21 by p53 induction attenuates the cell death in the quercetin-treated A549 cells (Kuo et al., 2004). These different observations may be due to the cell type and cell content specificity of apoptosis inducers and their subsequent signaling transduction pathways. Although our result indicated that plumbagin treatment caused an increase of p21 expression and a decrease of DNA repair resulting in cell death in mouse embryonic fibroblast cells. However, p21 has also been reported to influence the outcome of the p53 response to DNA damage and play a protective role on survival signal against apoptosis (Seoane et al., 2002; Kuo et al., 2004). The up-regulation of p21 by p53 induction attenuates the cell death in the quercetin-treated A549 cells (Kuo et al., 2004). These different observations may be due to the cell type and cell content specificity of apoptosis inducers and their subsequent signaling transduction pathways. Although our result indicated that plumbagin treatment caused an increase of p21 expression and a decrease of DNA repair resulting in cell death in mouse embryonic fibroblast cells. However, p21 has also been reported to influence the outcome of the p53 response to DNA damage and play a protective role on survival signal against apoptosis (Seoane et al., 2002; Kuo et al., 2004). The up-regulation of p21 by p53 induction attenuates the cell death in the quercetin-treated A549 cells (Kuo et al., 2004). These different observations may be due to the cell type and cell content specificity of apoptosis inducers and their subsequent signaling transduction pathways. However, p21 has also been reported to influence the outcome of the p53 response to DNA damage and play a protective role on survival signal against apoptosis (Seoane et al., 2002; Kuo et al., 2004). The up-regulation of p21 by p53 induction attenuates the cell death in the quercetin-treated A549 cells (Kuo et al., 2004).

Mitochondrial apoptotic pathway has been described as an important signaling of apoptotic cell death for mammalian cells (Hengartner, 2000). Following the treatment of A549 cells with plumbagin, we observed that plumbagin treatment resulted in a significant increase of Bax and Bak, Bcl-Xs expression, and a decrease of Bcl-2 and Bcl-XL, suggesting...
that changes in the ratio of proapoptotic and antiapoptotic Bel-2 family proteins might contribute to the apoptosis pro-
motion activity of plumbagin. In addition, elevation of phos-
pho-Bel-2 (Ser70) by plumbagin treatment further helps reduce its ability to bind with Bax and enhance the translo-
cation of Bax from cytosol to mitochondria, leading to an 
enhanced susceptibility of the cells to apoptosis (Ishikawa et 
al., 2003; Zu et al., 2005). However, phosphorylation of Bel-2 
at Ser70 has also been reported to be required for Bel-2's 
antiapoptotic activity upon IL-3 and etoposide treatment (Ito 
et al., 1997; Deng et al., 2001). The influence of Bel-2 phos-
phorylation thus requires further investigation. Our finding 
also showed a collapse of ΔVm, a substantial release of cyto-
chrome c, and the activation of caspase-9 after A549 cells 
were treated with plumbagin. These occurrences of mito-
ochondria apoptotic events are correlated with the modulation 
of plumbagin on Bel-2 family proteins. These results confirm 
that plumbagin-induced apoptosis is associated with regulation 
of Bel-2 family proteins.

Activation of the JNK pathways has long been associated 
with the apoptotic response induced by several DNA-damag-
ing agents (Liu and Lin, 2005). The proapoptotic targets of 
the activated JNK are not clearly defined, but the phosphor-
ylation of transcription factors such as c-Jun and p53, as well 
as pro- and antiapoptotic Bel-2 family members such as Bim 
and Bel-2, has been suggested to be of importance (Fuchs et 
al., 1998; Buschmann et al., 2000; Liu and Lin, 2005; Yoshida 
et al., 2005). Phosphorylation of human p53 in the N-termi-
nal domain results in enhancement of transcriptional activity 
and prolongation of p53 half-life by inhibiting p53-MDM2 
complex formation (Fuchs et al., 1998; Buschmann et al., 
2000). In this report, we have shown that treatment of A549 
cells with plumbagin resulted in the accumulation of phos-
pho-JNK in both in vitro and in vivo. This JNK activation 
correlated well with the plumbagin-induced increase of JNK 
activity as measured by the JNK substrate phospho-c-Jun.

Furthermore, we observed that blocking the plumbagin-
duced activation of JNK1/2 by SP600125 could prevent p53 
phosphorylation (Ser15) and enhance p53-MDM2 
interaction, suggesting that plumbagin-induced JNK activation 
contributes to the stabilization of p53 function by Ser15 phos-
phorylation, which decreases the interaction of p53 and 
MDM2. This suggestion was strongly supported by the inhibi-
tion of the duration and phosphorylation of p53 (Ser15) by 
SP600125 treatment. Our results indicated that the Ser392 
and Ser15 phosphorylation of p53 was also observed in plumb-
agin A549 cells, but SP600125 did not affect Ser392 phos-
phorylation on p53. Therefore, the upstream regulators and 
effect of p53 Ser392 phosphorylation require further investi-
gation. Previous study has reported that Bel-2 is inactivated 
by phosphorylation on three serine residues (Thr69, Ser70, 
and Ser87) via JNKs (Yamamoto et al., 1999). Our results 
showed that exposure of A549 cells to plumbagin led to con-
current phosphorylation of Bel-2 at Ser70 and SP600125 
pretreatment inhibited Bel-2 phosphorylation, suggesting 
that the activation of JNK induced by plumbagin is involved 
in the modulation of Bel-2. Moreover, the JNK inhibitor 
SP600125 prevented plumbagin-induced G1/M arrest and 
apoptosis, further suggesting that the cooperation of JNK 
with p53 and the mitochondrial apoptotic pathway play a 
crucial role in plumbagin-induced G1/M arrest and apoptosis.

Although SP600125 was described as an inhibitor of the 
JNK pathway for the treatment of autoimmune, inflamma-
tory, and neurodegenerative diseases and shown to be selec-
tive for JNK1/2 (Bennett et al., 2001), it has also been re-
ported to exhibit nonspecific inhibition on several cell cycle 
and apoptosis-related enzymes, including serum- and glu-
corticoid-induced kinase, p70 ribosomal protein S6 kinase, 
AMP-activated protein kinase, Cdk2, and dual-specificity, 
yrosine-phosphorylated and regulated kinase 1A (Bain et 
al., 2003). Therefore, the influence of nonspecific inhibition 
of SP600125 on plumbagin-mediated cell cycle arrest and apo-
ptosis induction could be further investigated.

In conclusion, the present study demonstrates that human 
nonsmall cell lung cancer A549 cells are highly sensitive to 
growth inhibition by plumbagin both in vitro and in vivo 
experimental models; reduced survival of A549 cells after 
exposure to plumbagin is associated with G1/M phase cell 
cycle arrest and apoptosis induction; plumbagin can inhibit 
cell cycle progression at the G1/M phase by increasing p21 
expression in a p53-dependent manner and by decreasing the 
expression of Cdc2, Cdc25C, and cyclinB1; plumbagin-in-
duced cell growth inhibition in the A549 cells is mediated by 
activation of JNK, which stabilizes p53 by phosphorylation 
of p53 at Ser15 and decreasing the interaction of p53 and 
MDM2; and JNK also phosphorylates Bel-2, leading to alter 
function of Bel-2 to apoptosis. These findings suggest that 
plumbagin may be a promising chemopreventive agent 
against human nonsmall cell lung cancer.
