ABSTRACT
Zonisamide (ZNS; 3-sulfamoylmethyl-1,2-benzisoxazole), as one of the newer antiepileptic drugs, has been demonstrated its broad-spectrum clinical efficacy on various neuropsychiatric disorders. However, little is known regarding the mechanism of ZNS actions on ion currents in neurons. We thus investigated its effect on ion currents in differentiated hippocampal 19-7 cells. In whole-cell configuration of patch-clamp technology, the ZNS (30 μM) reversibly increased the amplitude of K+ outward currents, and paxilline (1 μM) was effective in suppressing the ZNS-induced increase of K+ outward currents. In inside-out configuration, ZNS (30 μM) applied to the intracellular face of the membrane did not alter single-channel conductance; however, it did enhance the activity of large-conductance Ca2+-activated K+ (BKCa) channels primarily by decreasing mean closed time. In addition, the EC50 value for ZNS-stimulated BKCa channels was 34 μM. This drug caused a left shift in the activation curve of BKCa channels, with no change in the gating charge of these channels. Moreover, ZNS at a concentration greater than 100 μM also reduced the amplitude of A-type K+ current in these cells. A simulation modeling based on hippocampal CA3 pyramidal neurons (Pinsky-Rinzel model) was also analyzed to investigate the inhibitory effect of ZNS on the firing of simulated action potentials. Taken together, this study suggests that, in hippocampal neurons during the exposure to ZNS, the ZNS-mediated effects on BKCa channels and A-type K+ current could be potential mechanisms through which it affects neuronal excitability.

Zonisamide (ZNS) is a benzisoxazole derivative with a non-arylamine sulfonamide group and is chemically unrelated to other antiepileptic drugs. It has been characterized as having broad-spectrum antiepileptic and neuroprotective effects (Leppik, 2004; Baulac, 2006). Previous reports have demonstrated the ability of this drug to block voltage-dependent Na+ channels and T-type Ca2+ channels (Schauf, 1987; Suzuki et al., 1992; Leppik, 2004). It also has been shown to inhibit the ryanodine-induced increase in basal levels of glumamate and GABA in the rat hippocampus (Yoshida et al., 2005). In addition, ZNS has been reported as potentially blocking glutamate activity in the frontal cortex (Huang et al., 2005) and the firing of action potentials in spinal cord neurons (Rock et al., 1989). A recent report showed that ZNS could improve depressive symptoms in acute bipolar depression (Ghaemi et al., 2006). However, the mechanisms through which this drug can halt seizures or modulate mood activity are largely unknown, despite its increased use in the treatment of epilepsy or bipolar disorders.

The large-conductance Ca2+-activated K+ (BKCa) channels, the products of a nearly ubiquitous, alternatively spliced gene (SLO or KCNMA1) (Butler et al., 1993), are distinguished from other K+ channels in that they are gated open in response to Ca2+ binding to sites located inside of the channel, as well as by depolarized membrane potentials (Ghatta et al., 2006; Wu et al., 2006). Their activities provide a link between the metabolic and electrical state of cells because they are sensitive to stimulation by increased intracellular Ca2+. BKCa channels in hippocampal pyramidal cells have been identified for their collaborative effect with voltage-gated K channels in repolarizing spike and fast afterhyperpolarization.
perpoliarization (Storm, 1990; Shao et al., 1999). In addition, riluzole and cilostazol have been reported to enhance the activity of BKCa channels in pituitary tumor (GH3) cells (Wu and Li, 1999; Wu et al., 2004).

A recent study has demonstrated that mutation of the pore-forming α-subunit of BKCa channels could cause generalized epilepsy, paroxysmal dyskinesia (Du et al., 2005), and mental deficiency disorder such as autism (Laumonnier et al., 2006). In addition, the increased activity of BKCa channels, possibly associated with the peripheral antinociceptive action of metamizol and meloxicam (Ortiz et al., 2003, 2005), could counteract the deleterious effects of excitatory neurotransmitters following neurotoxic or ischemic injuries as well (Gribkoff et al., 2001; Ghatta et al., 2006). However, it remains unknown whether ZNS, as a potential neuropsychiatric modulator, produces any effects on the activity of these channels.

The hippocampal neuron-derived H19-7 cell line is known to possess the characteristics of hippocampal neurons (Morrione et al., 2000; Bhargava et al., 2002). This cell line has been used for studies on the development, plasticity, and commitment in hippocampal neurons (Morrione et al., 2000; Bhargava et al., 2002). Therefore, the goals of this study were to examine the effect of ZNS on K+ outward current in differentiated hippocampal H19-7 cells, to address the issue of whether this drug can affect the activity and kinetic properties of BKCa channels, and to determine whether it affects other types of ion currents present in these cells. Interestingly, these results indicate that ZNS can directly enhance the activity of BKCa channels.

**Materials and Methods**

**Cell Preparation.** The H19-7 cell line was originally derived from hippocampi dissected from embryonic day 17 Holtzman rat embryos and immortalized by retroviral transduction of temperature-sensitive tsA58 SV40 large T antigen. This cell line was obtained from American Type Culture Collection (CRL-2526; Manassas, VA) (Morrione et al., 2000; Huang et al., 2004). Cells were maintained in Dulbecco’s modified Eagle’s medium with 4 mM L-glutamine adjusted to contain 1.5 g/l sodium bicarbonate and 4.5 g/l glucose supplemented with 10% fetal bovine serum, 200 μg/ml G418, and 1 μg/ml puromycin in flasks that were coated with 15 μg/ml poly-L-lysine. They were equilibrated in a humidified atmosphere of 5% CO2/95% at an air temperature with a permissive temperature of 34°C. The experiments were generally performed after 5 days of subcultivation (60–80% confluence) with cells obtained from passages 2 and 4.

**Cell Differentiation.** For differentiation experiments, hippocampal H19-7 cells were plated at a density of 105 cells/35-mm plate in a medium containing serum at 34°C. After 18 h, the cells were washed extensively and then shifted to a nonpermissive temperature (39°C) in N2 serum-free medium (i.e., Dulbecco’s modified Eagle’s medium high glucose medium supplemented with 0.11 mg/ml sodium pyruvate, 2 mM glutamine, 0.1 mg/ml transferrin, 20 nM progesterone, 0.1 mM putrescine, and 30 nM sodium selenite), supplemented with 50 ng/ml insulin-like growth factor-1 (Life Technologies, Grand Island, NY). After 48 h, the cells were harvested and observed for neurite formation and subsequent electrophysiological experiments (Kim et al., 1997; Morrione et al., 2000). Therefore, rat hippocampal neurons-derived H19-7 cells could either proliferate at the permissive temperature of 34°C in response to insulin-like growth factor or differentiate to a neuronal phenotype in N2 medium at the nonpermissive temperature of 39°C (Kim et al., 1997; Morrione et al., 2000; Huang et al., 2006).

**Electrophysiological Measurements.** Immediately before each experiment, differentiated H19-7 cells were dissociated, and an aliquot of cell suspension was transferred to a recording chamber positioned on the stage of an inverted microscope (DM IL; Leica Microsystems, Wetzlar, Germany). Cells were bathed at room temperature (20–25°C) in normal Tyrode’s solution containing 1.8 mM CaCl2. The recording pipettes were pulled from Kimax-51 glass capillaries (Kimble Glass, Vineland, NJ) using a two-stage microelectrode puller (PP-830; Narishige, Tokyo, Japan), and the tips were fire-polished with a Narishige MF-83 (Narishige). When filled with pipette solution, their resistance ranged between 3 and 5 MΩ. Ion currents were recorded in a whole-cell or inside-out configuration of the patch-clamp technique, using an RK-400 patch-clamp amplifier (Bio-Logic, Claiux, France) (Huang et al., 2006). All potentials were corrected for liquid junction potential, a value that would always develop at the tip of the pipette when the composition of the pipette solution was different from that in the bath. Tested drugs were applied through perfusion or added to the bath to obtain the final concentration indicated.

**Data Recordings and Analyses.** The signals consisting of voltage and current tracings were displayed on an analog/digital oscilloscope (HM 507; Hamag Inc., East Meadow, NY). The data were stored online in a laptop computer through an analog/digital interface (Digidata 1322A; Molecular Devices, Union City, CA), controlled by a commercially available software package (pCLAMP 9.0; Molecular Devices). The sampling rate for electrophysiological measurements was 10 kHz. Currents were low-pass filtered at 1 or 3 kHz. Ion currents recorded during experiments were stored and analyzed subsequently using pCLAMP 9.0 software (Molecular Devices). Origin 7.5 software (Microcal Software, Inc., Northampton, MA), Sigmaplot 7.0 software (SPSS, Inc., Apex, NC), or custom-made macros in Excel 2003 (Microsoft, Redmond, WA). The pCLAMP-generated voltage-step protocols were generally used to examine the current-voltage (I-V) relations for ion currents.

To calculate concentration-dependent stimulation of ZNS on the activity of BKCa channels, H19-7 cells were bathed in a high-K+ (145 mM) solution, and inside-out configuration was performed. Each excised patch was held at +60 mV, and the bath medium contained 0.1 μM Ca2+. The concentration-dependent effect of ZNS at different concentrations (3–100 μM) was fitted with a Hill function. That is, relative open probability = (Emax × [C]nH)/(EC50^nH + [C]nH), where [C] represents the ZNS concentration, nH and EC50 are Hill coefficients and the ZNS concentration needed to increase channel activity by 50%, respectively; and Emax is the ZNS-induced maximal stimulation of BKCa channels.

Single-channel currents of BKCa or KATP channels were analyzed using pCLAMP 9.0 software (Molecular Devices). Multigaussian adjustments of the amplitude distributions between channels were used to determine unitary currents. The functional independence between channels was verified by comparing the observed stationary probabilities with the values calculated according to binomial law. The number of active channels in the patch N was counted at the end of each experiment and then used to normalize opening probability at each potential. The open probabilities were evaluated using an iterative process to minimize the χ2 calculated with a sufficiently large number of independent observations. The open or closed distribution of the channel was fit with a one- or two-exponential function.

The plots of the open probability of BKCa channels, as a function of membrane potential were constructed and fit with a Boltzmann function using nonlinear regression analysis with the Origin 7.5 (Microcal). That is, relative open probability = nP/(1 + exp(−(V − V1/2/k))], where nP = the maximal probability of channel openings, V = the membrane potential in mV, V1/2 = the membrane potential for half-maximal activation, and k = the slope factor of the activation curve.

The averaged results are presented as the mean values ± S.E.M. The paired or unpaired Student’s t test and one-way analysis of

The amplitude of $I_K$ evoked by the ramp pulse was significantly increased (Fig. 1). For example, at the level of $+80 \text{ mV}$, ZNS (30 μM) significantly increased the amplitude of $I_K$ from 795 ± 59 to 1509 ± 74 pA ($p < 0.05, n = 6$). In addition, ZNS (30 μM) increased the slope conductance of $I_K$ at the level of $+40 \text{ mV}$ from 16.7 ± 2.3 (n = 5) to 24.2 ± 3.5 (n = 5) nS and at the level of $+80 \text{ mV}$ from 18.4 ± 2.5 to 35.7 ± 3.6 nS (n = 5). After washout of ZNS, the amplitude of $I_K$ returned to 822 ± 31 pA (n = 5). A further application of 1 μM paxilline could reduce $I_K$ to 812 ± 63 pA ($p < 0.05, n = 5$). In addition, iberiotoxin (200 nM), but not apamin (200 nM), significantly reversed the ZNS-induced increase of $I_K$. In addition, the value for reversal potential of $I_K$ measured in the presence of ZNS or ZNS plus paxilline was around −75 mV. The results suggest that the amplitude of $I_K$ in response to the ramp pulses can be sensitive to increases in ZNS. The ZNS-induced increase of $I_K$ can be blocked by paxilline or iberiotoxin.
Stimulatory Effect of ZNS on the Activity of BK$_{ca}$ Channels in Differentiated H19-7 Cells. Paxilline and iberiotoxin, known inhibitors of BK$_{ca}$ channels, could reverse ZNS-stimulated $I_K$. The increased macroscopic $I_K$ could be due to the increased open probability, an increase in the number of active channels, or both. The effect of ZNS on BK$_{ca}$ channel activity in these cells was further investigated (Fig. 2). In these experiments, single-channel recordings with an inside-out configuration were performed in symmetrical K$^+$ solution (145 mM) (Fig. 2A). Bath medium contained 0.1 $\mu$M Ca$^{2+}$, and holding potential was held at +60 mV. When ZNS (100 $\mu$M) was applied to the intracellular surface of the excised patch, the channel activity was significantly increased to 0.015 $\pm$ 0.004 ($n = 5$) from a control of 0.004 $\pm$ 0.001 ($n = 5$, $p < 0.05$). A further application of paxilline (1 $\mu$M) could decrease the channel activity to 0.005 $\pm$ 0.001 ($n = 5$). The channel activity in paxilline (1 $\mu$M) alone was 0.003 $\pm$ 0.001 ($n = 5$). Application of ZNS (3–1000 $\mu$M) was found to enhance the probability of channel openings in a concentration-dependent manner. The half-maximal concentration required for the stimulatory effect of ZNS on BK$_{ca}$ channel activity was 34 $\mu$M, and Hill coefficient was 1.2. Thus, the ZNS-induced increase in the amplitude of $I_K$ in these cells could be associated with its increase in the open probability of BK$_{ca}$ channels, rather than changes in the number of active channels.

Lack of Effect of ZNS on Single-Channel Conductance of BK$_{ca}$ Channels. In the next series of experiments, the effect of ZNS on single-channel conductance was investigated. In inside-out configuration, the cells were bathed in symmetrical K$^+$ solution (145 mM), and bath medium contained 0.1 $\mu$M Ca$^{2+}$. Figure 3A illustrates averaged I-V relationships of BK$_{ca}$ channels obtained in the absence and presence of ZNS (30 $\mu$M). The single BK$_{ca}$ channel conductance calculated from a linear I-V relationship in control (i.e., in the absence of ZNS) was 166 $\pm$ 11 pS ($n = 8$) with a reversal potential of 0 $\pm$ 2 mV ($n = 8$). The value of single-channel conductance was not found to differ significantly from that (168 $\pm$ 10 pS, $n = 8$, $p < 0.05$) measured during the exposure to ZNS (30 $\mu$M). These results indicate that this drug does not cause any modification in single-channel conductance, despite its ability to increase the open probability of these channels.

Effect of ZNS on the Activation Curve of BK$_{ca}$ Channels. Figure 3B shows the activation curve of BK$_{ca}$ channels in the absence and presence of ZNS (30 $\mu$M). The plot of open probability of channel openings as a function of membrane potential was fitted with a Boltzmann function as described under Materials and Methods. In control, $n_p = 1$, $V_{1/2} = 56 \pm 5$ mV, and $k = 116 \pm 21$ mV ($n = 6$), whereas in the presence of ZNS (100 $\mu$M), $n_p = 1.6 \pm 0.2$, $V_{1/2} = 42 \pm 6$ mV, and $k = 115 \pm 19$ mV ($n = 6$). The data thus indicate that the ZNS-increased channel activity can be accompanied by a significant shift of the steady-state activation toward less positive potentials, although the slope factor of activation curve remained unaltered. Taken together, ZNS applied to the intracellular surface of the channel is capable of affecting the activation curve with no change in the gating charge of these channels.

Effect of Internal Ca$^{2+}$ Concentrations on ZNS-Stimulated BK$_{ca}$ Channel Activity. We next examined whether the ZNS-induced increase in the activity of these channels is associated with the level of internal Ca$^{2+}$ concentrations. In these experiments, when an excised patch was formed, various concentrations of Ca$^{2+}$ in the bath before and during exposure to ZNS (30 $\mu$M) were applied. As shown in Fig. 3C, the extent of ZNS-stimulated BK$_{ca}$ channels was not altered by changes in the level of intracellular Ca$^{2+}$ concentration. For example, at the level of +60 mV, ZNS (30 $\mu$M) increased the open probability at an internal Ca$^{2+}$ concentration of 0.1, 1, and 10 $\mu$M to a similar magnitude (i.e., 1.6-fold).

Effect of ZNS on Kinetic Behavior of BK$_{ca}$ Channels in Differentiated H19-7 Cells. The effect of ZNS on mean

![Fig. 2. Stimulatory effect of ZNS on BK$_{ca}$ channel activity in differentiated H19-7 cells. A, each excised patch was held at +60 mV. Channel activity during the exposure to ZNS (1 mM) was taken to be 1.0, and those at different concentrations of ZNS were then compared. B, relationship between the ZNS concentration and BK$_{ca}$ channel activity. Red smooth line, best fit to the Hill equation. The values for EC$_{50}$ and the Hill coefficient were 34 and 1.2 $\mu$M, respectively. C, bar graph showing the effect of ZNS, ZNS with addition of Pax, and Pax alone on $I_K$. open and closed time of BK<sub>Ca</sub> channels in these cells was examined and analyzed during recordings from patches showing only single-channel openings. As shown in Fig. 4, in control cells, the closed time histogram of BK<sub>Ca</sub> channels at +60 mV can be fitted by a two-exponential function with a mean closed time of 5.2 ± 0.9 and 54.5 ± 1.6 ms (n = 5). ZNS (30 μM) decreased the lifetime of the closed time to 3.2 ± 0.8 and 19.6 ± 1.1 ms (n = 5, p < 0.05). However, no change in the component of open time distribution was observed in the presence of ZNS (30 μM) (1.62 ± 0.05 versus 1.64 ± 0.04 ms, n = 5, p > 0.05). Taken together, the data suggest that the stimulation by this drug of BK<sub>Ca</sub> channels in these cells is largely due to an increase in open probability accompanied by the decreased closed time.

**Effect of Riluzole on BK<sub>Ca</sub> Channels in Differentiated Hippocampal H19-7 Cells.** Riluzole has been previously reported as stimulating BK<sub>Ca</sub> channels (Wu and Li, 1999). We also examined whether the stimulatory effects of ZNS and riluzole on these channels are additive. Interestingly, as shown in Fig. 5, riluzole (30 μM) increased the channel open probability; however, a subsequent application of ZNS (30 μM) did not increase the channel activity further. Riluzole (30 μM) significantly increased the probability of channel openings from 0.12 ± 0.02 to 0.24 ± 0.03 (n = 6, p < 0.05).

**Fig. 3.** Effect of ZNS on the I-V relationship and the Ca<sup>2+</sup> sensitivity of BK<sub>Ca</sub> channels in differentiated H19-7 cells. Experiments in excised patches were conducted in symmetrical K<sup>+</sup> solution (145 mM) and a bath medium containing 0.1 μM Ca<sup>2+</sup>. A, averaged I-V relationship of BK<sub>Ca</sub> channels in the absence (□) and presence (●) of 100 μM ZNS. Data are the mean ± S.E.M. (n = 6–10). Notably, there is no significant change in single-channel conductance between the absence and presence of ZNS. Fig. 6. Inhibitory effect of ZNS on voltage-dependent L-type Ca<sup>2+</sup> current (I<sub>Ca,L</sub>) in differentiated H19-7 cells. In these experiments, the cells were bathed in normal Tyrode’s solution that contained 1.8 mM CaCl<sub>2</sub>, 1 mM tetrodotoxin, and 10 mM tetraethylammonium chloride. The recording pipettes were filled with a Cs<sup>+</sup>-containing solution. A, original currents showing the effects of ZNS and ZNS plus nifedipine on I<sub>Ca,L</sub>. The cell was depolarized from −50 to 0 mV at a rate of 0.05 Hz. B, bar graph showing the effect of ZNS on the amplitude of I<sub>Ca,L</sub> with or without addition of nifedipine. ZNS, 300 μM; nifedipine (Nif), 0.3 μM. *, significantly different from control (p < 0.05). **, significantly different from the ZNS-alone group (p < 0.05).

Zonisamide; Ril, 30 μM riluzole, from the riluzole-alone group. /H11569/H11569, significantly different from ZNS-alone group. The question may arise whether a ZNS-induced increase in whole-cell I<sub>Ca,L</sub> is associated with an increased Ca<sup>2+</sup> influx through voltage-dependent Ca<sup>2+</sup> channels. ZNS has been previously reported as blocking Ca<sup>2+</sup> current (Suzuki et al., 1992). The effect of ZNS on the amplitude of L-type Ca<sup>2+</sup> current (I<sub>Ca,L</sub>) in differentiated H19-7 cells was thus assessed. In these experiments, cells were bathed in normal Tyrode’s solution containing 1.8 mM CaCl<sub>2</sub>, and the recording pipettes were filled with Cs<sup>+</sup>-containing solution. Cell exposure to ZNS (30 μM) did not affect the peak amplitude of I<sub>Ca,L</sub>. However, ZNS at a concentration of 300 μM resulted in a decrease in I<sub>Ca,L</sub> (Fig. 6). For example, when cells were depolarized from −50 to 0 mV, the peak amplitude of I<sub>Ca,L</sub> was slightly but significantly decreased from 85 ± 12 to 79 ± 11 pA (n = 5, p < 0.05). In addition, a further application of nifedipine (0.3 μM), a known blocker of I<sub>Ca,L</sub>, almost abolished the amplitude of I<sub>Ca,L</sub>. Thus, the results indicate that this drug can stimulate Ca<sup>2+</sup>-activated K<sup>+</sup> current in a manner unlikely to be associated with an increase in the amplitude of I<sub>Ca,L</sub>.

Effect of ZNS on Rapidly Inactivating A-Type K<sup>+</sup> Current in Differentiated H19-7 Cells. Previous studies at our laboratory have demonstrated that lamotrigine, another antiepileptic drug, could block A-type K<sup>+</sup> current (I<sub>K</sub>) in these cells in a concentration- and state-dependent manner (Huang et al., 2004). In this study, we further examined whether ZNS causes any effect of I<sub>K</sub>. As shown in Fig. 7, ZNS at a concentration of 100 or 300 μM could block the amplitude of I<sub>K</sub> significantly. When the cells were exposed to ZNS, the amplitude of I<sub>K</sub> was suppressed throughout the entire voltage-clamp step. The averaged I-V relations for the peak amplitude of I<sub>K</sub> in the absence and presence of ZNS are shown in Fig. 7B. The results indicate that ZNS at a concentration greater than 100 μM is able to block I<sub>K</sub> in these cells.
In this modeled neuron, when the conductance of Ca$^{2+}$ was decreased, along with the decreased firing of action potentials (Fig. 8A). When the conductance of Ca$^{2+}$ was decreased from 18 to 17 nS, the peak amplitude of $I_{Na}$ was readily reduced, along with the decreased firing of action potentials (Fig. 8A). When the conductance of Ca$^{2+}$-activated K$^+$ current was increased from 20 to 40 nS, the frequency of action potential firing was further reduced (Fig. 8B). As a result, the reduced $I_{Na}$ and the increased Ca$^{2+}$-activated K$^+$ current, which mimics ZNS action, can combine to cause a reduction in the firing of neuronal action potentials. The simulation results can be used to predict that the activity of BK$_{Ca}$ channels could contribute to the electrical behavior of hippocampal neurons.

**Discussion**

The major findings of this study are as follows. First, in differentiated hippocampal H19-7 cells, ZNS, a newer antiepileptic drug, increased the amplitude of K$^+$ currents, which mimics ZNS action, could decrease the firing of action potentials in modeled hippocampal neurons. The effects on ion channels could be important mechanisms underlying ZNS-induced action.

The concentration-dependent stimulation of BK$_{Ca}$ channel activity with an EC$_{50}$ value of 34 $\mu$M was observed in the presence of ZNS. This concentration of ZNS is compatible with clinically relevant concentrations, ranging from 50 to 200 $\mu$M (Peters and Sorkin, 1993; Tasaki et al., 1995; Oomen and Mathews, 1999; Huang et al., 2005). The observed effect of ZNS in this study is likely to occur at a concentration achievable in humans. It is thus reasonable to assume that BK$_{Ca}$ channels present in neurons are a relevant "target" for the action of ZNS. The ability of ZNS to activate BK$_{Ca}$ channels may constitute an important component regulating neuronal function, aiding in understanding the broad-spectrum efficacy in epilepsy and various neuropsychiatric disorders.

Our study demonstrates that ZNS does not modify single-channel conductance of BK$_{Ca}$ channels, although it increases the channel open probability significantly. The increased am-

**Effects of ZNS on Repetitive Firing of Action Potentials in Modeled Hippocampal CA3 Pyramidal Neurons.** To determine how ZNS alters the discharge pattern of hippocampal neurons and to address questions that are difficult to be experimentally studied, a simulation model, originally derived from Pinsky and Rinzel (1994), was also implemented. ZNS has been previously reported to block voltage-dependent Na$^+$ current ($I_{Na}$) (Schauf, 1987; Leppik, 2004). In this modeled neuron, when the $I_{Na}$ conductance was decreased from 18 to 17 nS, the peak amplitude of $I_{Na}$ was readily reduced, along with the decreased firing of action potentials (Fig. 8A). When the conductance of Ca$^{2+}$-activated K$^+$ current was increased from 20 to 40 nS, the frequency of action potential firing was further reduced (Fig. 8B). As a result, the reduced $I_{Na}$ and the increased Ca$^{2+}$-activated K$^+$ current, which mimics ZNS action, can combine to cause a reduction in the firing of neuronal action potentials. The simulation results can be used to predict that the activity of BK$_{Ca}$ channels could contribute to the electrical behavior of hippocampal neurons.

**Fig. 7.** Inhibitory effect of ZNS on $I_{Na}$ in differentiated H19-7 cells. Cells were bathed in Ca$^{2+}$-free solution containing tetrodotoxin (1 $\mu$M) and CdCl$_2$ (0.5 mM). A, original current traces showing the effect of ZNS (100 and 300 $\mu$M) on $I_{Na}$ in these cells. The cells were depolarized from −50 to +50 mV with a duration of 300 ms. B, averaged I-V relationships of $I_{Na}$ in the absence and presence of ZNS. Each point represents the mean ± S.E.M. ($n = 5–7$).

**Fig. 8.** Simulation modeling used to mimic ZNS effects on repetitive firing of action potentials in hippocampal neurons. The model was developed based on the electrophysiological properties of hippocampal CA3 pyramidal neurons as described under Materials and Methods. In A, when the $I_{Na}$ conductance was arbitrarily decreased from 18 to 17 nS, the amplitude of $I_{Na}$ was readily reduced, together with the decrease in the firing of neuronal action potentials. In B, when the conductance of Ca$^{2+}$-activated K$^+$ current was increased from 20 to 40 nS in the continued presence of reduced $I_{Na}$ conductance, which resembles the effects of ZNS, the action potential firing frequency was further reduced, together with the increased amplitude of Ca$^{2+}$-activated K$^+$ current in this modeled neuron. The horizontal bar shown in each panel indicates the reduction of $I_{Na}$ conductance in combination with or without increased conductance of Ca$^{2+}$-activated K$^+$ current.
plitude of macroscopic $I_K$ is thought to be primarily due to the increased probability of channel openings accompanied by a decrease in mean closed time. In addition, when applied to the internal face of the membrane, it did not merely increase the activity of $BK_{Ca}$ channels in the patch but also increased a shift of voltage sensitivity of the channel to less positive potentials. The sensitivity to this drug in neurons would be thus expected to depend on the prevailing level of resting potential, the firing rate of action potentials, or the ZNS concentration used.

It is noteworthy that, unlike the molecule of cilostazol, ZNS was found to possess an intramolecular hydrogen bond with a short interatomic distance and an aromatic ring poor of electrons, the properties of which are shared by other inhibitors of carbonic anhydrase (Tricarico et al., 2004). The present results also demonstrate that the stimulatory effect of ZNS and riluzole on the activity of $BK_{Ca}$ channels is not additive. Riluzole has been previously reported as an opener of $BK_{Ca}$ channels in pituitary tumor (GH3) cells (Wu and Li, 1999). It is likely that these two components, which are structurally related, may interact with the same binding site in the channel.

Previous reports have shown that some of the indole diterpenes, which are potent inhibitors of $BK_{Ca}$ channels, are associated with their tremorogenic activity (Knaus et al., 1994; Smith et al., 1997). Recent reports have demonstrated that compared with $\beta$ blocker, zonisamide is effective in treating essential tremor (Morita et al., 2005; Ondo, 2006). Further studies are needed to determine the extent to which ZNS-stimulated activity of $BK_{Ca}$ channels contribute to its treatment of essential tremor.

ZNS at a concentration greater than 100 $\mu$M was found to block $I_{Ca}$ in differentiated hippocampal H19-7 neurons. Lack of A-type $K^+$ channels has been proposed to decrease the seizure threshold in the cortical malformation of methylazoxymethanol-exposed rats (Castro et al., 2001). Although no report on ZNS-worsening seizures has been noted, ZNS has been recently reported to improve depressive symptoms in bipolar disorders (Ghaemi et al., 2006). Whether its inhibition of the $I_{Ca}$ channels has potential psychotropic benefits in treating underlying cellular disturbances in bipolar disorders, as described previously, remains to be further clarified.

Our simulation results also imply that both blockade of $I_{Ca}$ and direct stimulation of $BK_{Ca}$ channels caused by ZNS may synergistically act to affect the functional activity of hippocampal neurons in vivo. Taken together, in addition to the blockade of $I_{Ca}$, our results lead us to suggest that ZNS-mediated antiepileptic action could be partly associated with the direct stimulation of $BK_{Ca}$ channels expressed in hippocampal neurons.

Acknowledgments

We thank Okada Motohiro (Hirosaki University, Japan) for comments on zonisamide pharmacology. We also thank Ming-Wei Lin for technical assistance.
