ABSTRACT

The organic anion transporting polypeptide 1A2 (OATP1A2), a membrane drug transporter expressed on important organs (such as the brain, kidney, and intestine) may be a key element in the disposition of drugs. Previous studies demonstrated that it could transport a broad spectrum of substrates, including endogenous molecules and clinically relevant drugs, such as several β-blockers and 3-hydroxy-3-methylglutaryl-CoA reductase inhibitors. The primary objective of this study was to investigate OATP1A2 transport activity using rosuvastatin as a probe substrate and evaluate competitive inhibition of its transport by β-blockers. Rosuvastatin transport was saturable, with a Kᵣ of 60.2 µM. With the exception of carvedilol (IC₅₀ of 3.2 µM), all of the other β-blockers that were evaluated had a small or insignificant effect on OATP1A2-mediated uptake of rosuvastatin. Carvedilol differs from the other β-blockers by the tricyclic moiety in its chemical structure. As a secondary objective, the transport of a series of tricyclic compounds by OATP1A2 and their potential for rosuvastatin transport inhibition were evaluated. Tricyclic compounds were not OATP1A2 substrates. On the other hand, tricyclic compounds with a short aliphatic amine chain inhibited OATP1A2-mediated rosuvastatin transport. Our data suggest that these drugs may modulate the transport of OATP1A2 substrates and may affect drug actions.

Introduction

Organic anion transporting polypeptide 1A2 (OATP1A2) is a membrane drug transporter expressed on organs important for drug disposition. The mRNA expression is found to be the highest in the brain, followed by the kidney, liver, lung, and testes (Kullak-Ublick et al., 1995). OATP1A2 protein is found on the luminal membrane of the brain capillary endothelial cells, which make up the blood-brain barrier, apical membranes of cholangiocytes in the liver, apical membrane of the distal nephrons in the kidney, and apical membrane of enterocytes in the duodenum (Gao et al., 2000; Lee et al., 2005; Glaeser et al., 2007). OATP1A2 expression in the small intestine is controversial, as recent studies could not detect its presence in the entire intestine (Groer et al., 2013; Drozdzik et al., 2014). Due to its location, the following roles have been attributed to OATP1A2: distribution of substrates to the brain, reabsorption of substrates excreted in the bile, reabsorption or secretion of xenobiotics into urine, and oral absorption of xenobiotics.

OATP1A2 transports various endogenous molecules, such as bile salts and hormones (triiodothyronine, thyroxine, and steroid conjugates) (Kullak-Ublick et al., 1995, 1998; Fujiwara et al., 2001; Lee et al., 2005). Based on the endogenous substrates it transports and its localization, it has been proposed that OATP1A2 may be involved in the regulation of several physiologic processes. For instance, it may be implicated in the delivery of thyroid hormones to the brain and kidney as well as the removal of thyroid hormones from the periphery (Hagenbuch, 2007). In addition, it may play a role in bile acid transport, as a study has shown that OATP1A2 mRNA is upregulated in patients with cholestatic liver disease (Kullak-Ublick et al., 1997).

OATP1A2 can also transport several exogenous substances, including peptide agonists of the opioid receptor and bromosulphophthalein (Kullak-Ublick et al., 1995; Gao et al., 2000). Several clinically important drugs, such as fexofenadine, imatinib, methotrexate, pravastatin, and rosuvastatin, are also transported by OATP1A2 (Cvetkovic et al., 1999; Badagnani et al., 2006; Ho et al., 2006; Hu et al., 2008; Shirasaka et al., 2010). Rosuvastatin is a hydrophilic molecule and, therefore, depends on transporters to move across the plasma membrane. Rosuvastatin has a high affinity for OATP transporters, as its...
$K_m$ was determined to be 2.6, 4.0, 9.8, and 2.4 $\mu$M for OATP1A2, OATP1B1, OATP1B3, and OATP2B1, respectively (Ho et al., 2006). Finally, OATP1A2 is inhibited by various flavonoids, such as naringin, apigenin, kaempferol, quercetin, and several flavonoids found in green tea (Bailey et al., 2007; Mandery et al., 2010; Roth et al., 2011; Misaka et al., 2014).

Flavonoids are found in vegetables, fruits, and plants; thus, pharmacokinetic studies using flavonoids focused on intestinal interactions. Bailey et al. (2007) have demonstrated that ingestion of fexofenadine and a solution of naringin decreased fexofenadine maximum plasma concentration ($C_{max}$) and the area under the plasma concentration time curve (AUC). Misaka et al. (2014) have shown that green tea decreased nadolol $C_{max}$ and AUC. These interactions assume that OATP1A2 is an intestinal uptake transporter in the human intestine.

Single-nucleotide polymorphisms in the gene encoding OATP1A2, SLC01A2, resulting in impaired cell surface expression and reduced OATP1A2 activity have been discovered in healthy individuals (Lee et al., 2005; Badagnani et al., 2006; Laitinen and Niemi, 2011). This suggests that OATP1A2 may not play a fundamental role in physiologic functions but may act as a secondary transporter for endogenous molecules. However, there is evidence that OATP1A2 may be important in drug disposition, as Yamakawa et al. (2011) demonstrated that inatimib clearance is affected in chronic myeloid leukemia patients with the SLC01A2–361G>A genotype.

A previous study has proposed that several $\beta$-blockers are OATP1A2 substrates (Kato et al., 2009). Initially, their study aimed at determining the transporters involved in the gastrointestinal absorption of celiprolol to understand the food–drug interaction induced by citrus juices using an animal model. They demonstrated an increase in plasma concentrations of celiprolol in mdr1a/b−/− mice compared with wild-type mice. Using isolated tissues of the mouse small intestine, they demonstrated competitive inhibition between celiprolol and bromosulphathalein for transport from the apical to basolateral side. Their results suggested the involvement of P-glycoprotein and an influx transporter in the absorption of celiprolol. Subsequently, using Xenopus laevis oocytes, the uptake transporter involved was shown to be OATP1A2. In addition, they tested several other $\beta$-blockers and showed that acebutolol, atenolol, nadolol, sotalol, and labetalol are OATP1A2 substrates. More recently, a study has also shown that nadolol is transported by OATP1A2 in human embryonic kidney (HEK293) cells stably expressing the transporter (Misaka et al., 2014).

Considering the OATP1A2 location on important organs involved in drug disposition (such as the brain), it is of interest to investigate this transporter further. Based on current knowledge, the primary objectives of this study were to 1) assess rosvastatin as a probe substrate for OATP1A2, and 2) determine whether there is competition between rosvastatin and $\beta$-blockers for transport through OATP1A2. Considering the results obtained throughout the course of our studies, the secondary objectives were to 1) evaluate the transport of different tricyclic compounds through OATP1A2; and 2) determine whether there is competition between rosvastatin and tricyclic compounds for transport through OATP1A2. Experiments were conducted using a HEK293 cell line stably overexpressing OATP1A2. This in vitro model was used since it offers many advantages over transient models, such as stable expression, possibility for high-throughput screening, and ease of use once the cell line has been established.

**Materials and Methods**

Acebutolol hydrochloride, alprenolol tartrate salt, amitriptyline hydrochloride, atenolol, carbamazepine, carbazole, chlorpromazine hydrochloride, clomipramine hydrochloride, desipramine hydrochloride, imipramine hydrochloride, metoprolol tartrate salt, nadolol, naproxen, nortriptyline hydrochloride, phenothiazine, propranolol hydrochloride, timolol maleate salt, and trimipramine maleate salt were purchased from Sigma-Aldrich (St. Louis, MO). Carazolol hydrochloride, carvedilol, celiprolol hydrochloride, doxepin hydrochloride, and rosvastatin calcium salt were purchased from Toronto Research Chemicals (Toronto, ON, Canada). Sotalol hydrochloride was a gift from Bristol-Myers Squibb (Montreal, QC, Canada). All chemicals and solvents were obtained from Sigma-Aldrich, Fisher Scientific (Fair Lawn, NJ), or J.T. Baker (Center Valley, PA).

**Cell Culture.** HEK293-OATP1A2 and HEK293-VC cells were kindly provided by Dr. Markus Keiser and Dr. Werner Siegmund (Department of Clinical Pharmacology, Center of Drug Absorption and Transport, University Medicine Greifswald, Greifswald, Germany). The cells were cultured in minimum essential medium containing 10% fetal bovine serum, 1× nonessential amino acids, and 1× sodium pyruvate at 37°C and 5% CO₂. Cell culture media and supplements were purchased from Multicell Wisent Inc. (St.-Jean-Baptiste, QC, Canada), whereas fetal bovine serum was obtained from HyClone Thermo Scientific (Logan, UT).

**Uptake Assays and Competition Assays.** HEK293-OATP1A2 and HEK293-VC cells were seeded in tissue culture plates (6 or 12 well) previously treated with poly-L-lysine (Sigma-Aldrich). The number of cells seeded in 6- and 12-well plates was $1.5 \times 10^5$ and $7.5 \times 10^5$ cells/well, respectively. After 24 hours, the culture media was removed and the cells were preincubated with a warm transport buffer (142 mM NaCl, 5 mM KCl, 1 mM K₂HPO₄, 1.2 mM MgSO₄, 1.5 mM CaCl₂, 5 mM glucose, and 12.5 mM HEPES, pH 7.3) at 37°C for 5 minutes. Following the preincubation period, the cells were incubated with a transport buffer containing rosvastatin in the presence or absence of an inhibitor at 37°C for 2 minutes. After incubation, the cells were washed twice with phosphate-buffered saline (PBS) containing 10% acetonitrile followed by a final wash with PBS. Rosvastatin transport (60 $\mu$M) at different time points was done in 6-well plates by incubating HEK293-OATP1A2 and HEK293-VC cells. The $K_m$ and $V_{max}$ of rosvastatin transport through OATP1A2 was determined by incubating HEK293-OATP1A2 and HEK293-VC cells in 6-well plates with rosvastatin concentrations ranging from 10 to 250 $\mu$M. To determine whether a compound can block OATP1A2, HEK293-OATP1A2 and HEK293-VC cells were coincubated in 12-well plates with rosvastatin (150 $\mu$M), which was used as the probe substrate, in the absence or presence of different $\beta$-blockers (1.5–100 $\mu$M) or different tricyclic compounds (12.5 nM–250 $\mu$M). A concentration of 150 $\mu$M rosvastatin (three times the $K_m$ value) was selected to saturate the OATP1A2 transporter with the probe substrate. The inhibitory constant ($K_i$) of the tricyclic drugs for OATP1A2 was determined by incubating HEK293-OATP1A2 and HEK293-VC cells in 6-well plates with various concentrations of rosvastatin (25–250 $\mu$M) in the absence or presence of the tricyclic drugs (0.5–50 $\mu$M). Uptake of carvedilol was assessed in 12-well plates at a concentration of 2 $\mu$M for 2 minutes at 37°C. The preincubation and washing steps are the same as for rosvastatin.

The protein concentration was measured in three wells of cells lysed with 1% SDS + 0.2 N NaOH using the Pierce BCA protein assay kit from Thermo Scientific (Rockford, IL).

**Quantification of Rosvastatin by High-Performance Liquid Chromatography-UH.** The quantity of rosvastatin transported in the cells was measured by high-performance liquid chromatography with UV detection. The instrumentation consisted of a SpectraSystem P4000 pump, SpectraSystem AS3000 autosampler, Finnigan SpectraSystem UV6000 UV detector, and SpectraSystem SN4000 system controller from Thermo Electron Corporation (San Jose, CA). ChromQuest version 4.2.34 software was used for data acquisition (ThermoQuest DOHNASOJSTR31191)
samples were reconstituted in 500 l of 50 mM potassium phosphate monobasic, pH 3, and acetonitrile (57.43 v/v). The flow rate was set at 1.2 ml/min, and the column was heated at 40°C. Naproxen was used as the internal standard. The retention times of rosuvastatin and naproxen were 4.8 and 6.1 minutes, respectively. The peaks were monitored at a wavelength of 243 nm. The lowest limit of quantification was 25 ng/ml. The calibration curve was linear between 25 and 25,000 ng/ml (r^2 of 0.996). The interday coefficient of variation (CV) for the calibration curve using four levels of quality controls (25, 100, 2500, and 25,000 ng/ml) ranged between 3.9 and 7.8%. The interday accuracy ranged between 94.4 and 98.4%. The intraday CV for the four levels of quality control ranged between 1.1 and 13.6%. The intraday accuracy ranged between 84.5 and 101.4%.

After the final wash with PBS, the samples were processed as follows. The cells were lysed with methanol containing naproxen (100 ng/ml). The cell lysate was transferred to a 1.7-ml microtube, and the samples were spun down at a maximum speed for 10 minutes at room temperature. The supernatant was transferred to a culture borosilicate glass tube, evaporated to dryness, and reconstituted in 100 l of 10 mM ammonium formate, pH 3, and acetonitrile (57.43 v/v). A volume of 20 l per sample was injected.

**Quantification of Carvedilol by High-Performance Liquid Chromatography Fluorescence.** The same system was used for the quantification of carvedilol than for rosuvastatin, except for the detector, which was a SpectraSystem FL3000 fluorescence detector from Thermo Electron Corporation. The samples were separated on an Eclipse XDB-C8 column (150 x 4.6 mm, 5 M; Agilent Technologies, Santa Clara, CA). The mobile phase consisted of a mixture of 50 mM potassium phosphate monobasic, pH 3.5, and acetonitrile (60:40 v/v). The flow rate was set at 1.0 ml/min, and the column was heated at 50°C. Propranolol was used as the internal standard. The retention times of carvedilol and propranolol were 2.9 and 2.2 minutes, respectively. The excitation and emission wavelengths were 242 and 344 nm, respectively. After the final wash in PBS, the samples were processed similarly to the rosuvastatin samples, with the following exceptions: the cells were lysed with methanol containing propranolol (200 ng/ml), and the samples were reconstituted in 50 l of 50 mM potassium phosphate monobasic, pH 3.5. The lowest limit of quantification was 50 ng/ml. The calibration curve was linear over a concentration range of 50 to 2000 ng/ml (r^2 of 0.998). The interday CV for the calibration curve using four levels of quality controls (50, 80, 200, and 2000 ng/ml) ranged between 3.9 and 8.2%. The interday accuracy ranged between 95.3 and 99.3%. The intraday CV for the four levels of quality control ranged between 3.0 and 10.3%. The intraday accuracy ranged between 91.4 and 103.3%.

**Data Analysis.** The net transport of rosuvastatin through OATP1A2 was calculated by subtracting the value in the VC cells from the value in the OATP1A2 cells. The data were analyzed using GraphPad Prism 5 (GraphPad Software, La Jolla, CA). Each data point is expressed as the mean ± S.D. K_m and V_max were calculated by fitting the data to the Michaelis-Menten equation. IC_{50} values were calculated by fitting the data to the log(inhibitor) versus response equation, and the range given represents the 95% confidence interval. Transport inhibitions of different concentrations of rosuvastatin by increasing concentrations of inhibitors were plotted in a Dixon plot. Linear regression was used to fit each set of data, and the intercept of all lines represents the -K_i. The K_i was accurately calculated by the equations

\[ y = V_{\text{max}} \times \frac{x}{K_{\text{m,app}} + x} \]

\[ K_{\text{m,app}} = K_m \times \left(1 + \frac{l}{K_i}\right). \]

An initial value of 1.0 was set for all parameters. The rule for the initial value for K_m was set to 10*XMID, and V_max was set to 10*YMAX. A shared value for all data sets was set as a default constraint for K_m, K_i, and V_max, and a constant data set (= column title) was set for the parameter l.

**Results**

**Transport of Rosuvastatin through OATP1A2.** Rosuvastatin transport via OATP1A2 was characterized using a HEK293 cell model stably expressing this transporter. Transport during different time points demonstrated that rosuvastatin uptake was linear between 1 and 2 minutes (Fig. 1A). An incubation time of 2 minutes was chosen for all experiments, as it remains in the linear range. Overall, the transport activity varied from 1395 to 8056 pmol/mg protein per minute over a range of concentrations of 10–250 μM of rosuvastatin. A saturable transport was observed with a K_m of 60.2 ± 6.0 μM, the V_max was 9741 ± 543 pmol/mg protein per minute, and the intrinsic clearance was 161.8 μl/mg protein per minute (Fig. 1B).

**Effect of β-Blockers on Rosuvastatin Uptake through OATP1A2.** To determine whether β-blockers are OATP1A2 inhibitors, competition studies were performed using rosuvastatin as a probe substrate (Fig. 2). Carvedilol was the only β-blocker able to fully inhibit OATP1A2-mediated uptake of rosuvastatin, and it was the most potent inhibitor, with an IC_{50} of 3.2 μM. Metoprolol, propranolol, acebutolol, alprenolol,
celiprolol, nadolol, and timolol had a small effect on OATP1A2-mediated uptake of rosuvastatin. Given that complete inhibition could not be achieved by these β-blockers at the concentrations tested, the IC₅₀ could not be calculated appropriately. Sotalol and atenolol demonstrated no significant effect on rosuvastatin uptake.

**Effect of Tricyclic Compounds on Rosuvastatin Uptake through OATP1A2.** By observing the structures of all β-blockers tested, it can be noticed that carvedilol differs from the others by the presence of a tricyclic moiety in its structure (Fig. 3; Supplemental Fig. 1A). Inhibition studies were performed with compounds with a similar structure using rosuvastatin as the probe substrate to determine whether the tricyclic ring is responsible for carvedilol’s strong inhibitory effect on OATP1A2 (Fig. 3; Supplemental Figs. 1B and 2; Table 1). Carazolol exerted the strongest inhibition, with an IC₅₀ of 3.7 μM. The inhibition potencies were followed by clomipramine (IC₅₀ = 8.2 μM), amitriptyline (IC₅₀ = 11.7 μM), chlorpromazine (IC₅₀ = 12.0 μM), doxepin (IC₅₀ = 12.1 μM), trimipramine (IC₅₀ = 15.0 μM), imipramine (IC₅₀ = 16.9 μM), nortriptyline (IC₅₀ = 25.0 μM), and desipramine (IC₅₀ = 37.0 μM). Carbamazepine, carbazole, and phenothiazine exerted no significant effect on OATP1A2-mediated uptake of rosuvastatin.

**Transport of Tricyclic Compounds through OATP1A2.** Comparison between the structures of the compounds that inhibited OATP1A2 and those that exerted no effect reveals that a molecule composed of a tricyclic ring with a short aliphatic amine chain is able to inhibit OATP1A2 activity. As several tricyclic drugs inhibited rosuvastatin uptake, it was relevant to determine if they are also substrates of OATP1A2. Analytical methods were developed for each drug, and transport assays were conducted. Given that carvedilol showed the strongest inhibitory effect on rosuvastatin transport, it was the first tricyclic drug assessed. Incubation of carvedilol with HEK293-OATP1A2 and HEK293-VC showed no difference in intracellular concentrations of carvedilol between the two cell lines (Fig. 4). Thus, carvedilol is not a substrate of OATP1A2 but an inhibitor. Other tricyclic drugs, such as amitriptyline, doxepin, trimipramine, and imipramine, were also evaluated but it was found that none of the drugs were OATP1A2 substrates. Only the results for carvedilol are presented as an example since all graphs were similar.

**Determination of Inhibition Constant of Tricyclic Compounds.** The Kᵢ of previously identified inhibitors for OATP1A2 transport were determined using rosuvastatin as a probe substrate. A Dixon plot was drawn for each inhibitor, and the Kᵢ was calculated (Fig. 5; Supplemental Fig. 3; Table 2). Carvedilol showed the lowest Kᵢ value (1.1 μM), implying it as the strongest inhibitor evaluated. The inhibition potencies were followed by trimipramine (2.8 μM), carazolol (3.2 μM), clomipramine (3.3 μM), imipramine (3.5 μM), amitriptyline

Fig. 2. Inhibition of OATP1A2-mediated transport of rosuvastatin by different β-blockers. HEK293-OATP1A2 and HEK293-VC cells were coincubated with rosuvastatin (150 μM) and different β-blockers (1.5–100 μM; up to 200 μM for carvedilol) for 2 minutes at 37°C. The quantity of intracellular rosuvastatin measured was normalized to protein content. To obtain the net transport, values measured in the VC cells were subtracted from the values measured in OATP1A2-expressed cells. IC₅₀ values were calculated by fitting the data to the log(inhibitor) versus response equation in GraphPad Prism. (A) ●, metoprolol; ■, propranolol; ▲, acebutolol. (B) ●, alprenolol; ■, celiprolol; ▲, nadolol. (C) ●, timolol; ■, atenolol; ▲, sotalol. (D) ●, carvedilol. Each point represents the mean ± S.D. of triplicate from a single experiment. (3.7 μM), doxepin (4.7 μM), chlorpromazine (5.3 μM), desipramine (8.4 μM), and nortriptyline (12.0 μM).

**Discussion**

A method to study drug–drug interactions between substrates of OATP1A2 using rosuvastatin as a probe substrate was developed and validated. Inhibition studies between the probe substrate and different β-blockers demonstrated that carvedilol was the most potent inhibitor. The other β-blockers evaluated had little or no significant effects. Furthermore, a structure–activity relationship established from the tricyclic compounds evaluated demonstrated that the transport activity of OATP1A2 was inhibited by compounds composed of a tricyclic ring and short aliphatic amine chain. These compounds were not found to be transported by OATP1A2.

The $K_{m}$ of rosuvastatin for OATP1A2 in this study was determined to be 60.2 μM, which is higher than the previously published $K_{m}$ (2.6 μM) (Ho et al., 2006). Our results also show a superior efficiency ($V_{max}/K_{m}$) of 161.8 compared with 1 μl/mg protein per minute (Ho et al., 2006). This discrepancy may be explained by the different in vitro models employed. Ho et al. (2006) used transiently transfected HeLa cells, while a HEK293-OATP1A2 stable cell line was used in this study. The major setback with transiently transfected cells is the lack of reproducibility from one experiment to another. Variability may even arise within a single experiment from one well of transfected cells to another. A stable cell line offers uniformity within a cell population and simplicity once the cell line has been developed. Due to these advantages, a stable cell line was used in this study.

The β-blockers evaluated, with the exception of carvedilol, were not able to compete with rosuvastatin for OATP1A2

**Fig. 3.** Chemical structures of compounds evaluated. Structure of carvedilol, carazolol, amitriptyline, and propranolol and the list of structurally similar compounds evaluated.
transport. These results imply that they are either not substrates of OATP1A2, as previously reported, or they have a weaker affinity for the transporter than rosuvastatin. A $K_m$ of 84.3 μM for nadolol has been reported, which supports the second explanation (Misaka et al., 2014). It remains to be determined for the other β-blockers. Carvedilol blocked OATP1A2-mediated uptake of rosuvastatin very efficiently without being transported by it. Other compounds evaluated with a similar structure also blocked OATP1A2-mediated uptake of rosuvastatin. These results suggest that compounds composed of a tricyclic ring and short aliphatic amine chain could potentially block the transport of OATP1A2 substrates. Based on this structure-relationship finding, tricyclic antidepressants have been selected to further investigate OATP1A2 uptake and transport inhibition. Our results observed with the tricyclic antidepressants strongly suggest that these structural features appear to be determinant for the inhibition of OATP1A2 but not to mediate substrate uptake transport.

Drug–drug interaction studies involving the transporter have mainly focused on drug absorption since OATP1A2 expression has previously been detected at the duodenum by immunohistochemistry (Glaeser et al., 2007). Several publications demonstrated that fruit juices and green tea decreased the bioavailability of OATP1A2 substrates (Dresser et al., 2005; Bailey et al., 2007; Glaeser et al., 2007; Rebellio et al., 2012; Misaka et al., 2014). However, other publications failed to prove an interaction demonstrated in a cell model in humans (Eechoute et al., 2011). In addition, Misaka et al. (2014) showed that green tea decreased the $C_{\text{max}}$ and AUC of nadolol and their results suggest that the interaction is in part mediated by OATP1A2. In contrast, grapefruit juice, an established inhibitor of OATP1A2, did not have the same effect on nadolol (Misaka et al., 2013). A recent study looking at influx and efflux drug transporters in the small intestine using liquid chromatography–tandem mass spectrometry demonstrated that OATP1A2 was not expressed in any segment of the intestine and other influx transporters, such as OATP2B1, PEPT1, and OCT1, may be implicated in the absorption of drugs instead (Groer et al., 2013; Drozdzik et al., 2014). This may explain the inconsistency in studies where in vivo and in vitro data do not corroborate and different clinical studies using the same inhibitor have conflicting results.

As OATP1A2 is expressed on the luminal membrane of endothelial cells from the blood-brain barrier, it may potentially be involved in the distribution of drugs to the brain. Tricyclic antidepressants must cross the blood-brain barrier to reach their site of action, and we showed that these drugs are inhibitors of OATP1A2. It could be speculated that the coadministration of a tricyclic antidepressant with a central nervous system (CNS) drug substrate for OATP1A2 may lead to a drug–drug interaction when both drugs meet at the blood-brain barrier. It could result in a loss in efficacy by limiting their penetration to the brain. Cheng et al. (2012) conducted a structure-activity relationship study using triptan structural analogs and demonstrated that an amine atom was necessary for efficient uptake through OATP1A2 and that the uptake rate was the highest for a tertiary amine followed by a secondary and then primary amine. Likewise, tricyclic antidepressants, which are also CNS active drugs, share some general similarities with triptans and β-blockers, including an amine residue within their structure, a tricyclic ring, and a short aliphatic chain.

Taken together, the data in this study showed that compounds composed of a tricyclic ring with a short aliphatic amine chain inhibited OATP1A2 activity. Tricyclic antidepressants are a class of medication with such a structure, and

The values in parentheses represent the 95% confidence interval (see also Supplemental Fig. 3).
we demonstrated their strong inhibition on OATP1A2-mediated transport of rosuvastatin. Such an interaction may potentially be significant for CNS-active drugs that use OATP1A2 to cross the blood-brain barrier. Future work needs to be done to assess whether OATP1A2-mediated transport of CNS-active drugs can be blocked by tricyclic antidepressants. The clinical relevance of such an interaction needs to be investigated further as well.

Acknowledgments

The authors thank Dr. Markus Keiser and Dr. Werner Siegmund (Department of Clinical Pharmacology, Center of Drug Absorption and Transport, University Medicine Greifswald, Greifswald, Germany) for kindly providing the HEK293-OATP1A2 and the HEK293-VC cell lines.

Authorship Contributions

Participated in research design: Lu, Michaud, Turgeon.
Conducted experiments: Lu, Guilarte Moya, Leung.
Contributed new reagents or analytic tools: Gaudette.
Performed data analysis: Lu, Gaudette.
Wrote or contributed to the writing of the manuscript: Lu, Michaud, Turgeon.
