ABSTRACT

Acute liver failure (ALF) is a potentially life-threatening disorder without any effective treatment strategies. D-galactosamine (GalN)/lipopolysaccharide (LPS)-induced ALF is a widely used animal model to identify novel hepatoprotective agents. In the present study, we investigated the potential of a cannabinoid receptor 2 (CB2) agonist, JWH-133 [(6aR,10aR)-3-(1,1-dimethylbutyl)-6a,7,10,10a-tetrahydro-6,6,9-trimethyl-6 \textit{H}-dibenzo[b,d]pyran], in the amelioration of GalN/LPS-induced ALF. JWH-133 treatment protected the mice from ALF-associated mortality, mitigated alanine transaminase and proinflammatory cytokines, suppressed histopathological and apoptotic liver damage, and reduced liver infiltration of mononuclear cells (MNCs). Furthermore, JWH-133 pretreatment of M1/M2-polarized macrophages significantly increased the secretion of anti-inflammatory cytokine interleukin-10 (IL-10) in M1 macrophages and potentiated the expression of M2 markers in M2-polarized macrophages. In vivo, JWH-133 treatment also suppressed ALF-triggered expression of M1 markers in liver MNCs, while increasing the expression of M2 markers such as Arg1 and IL-10. microRNA (miR) microarray analysis revealed that JWH-133 treatment altered the expression of only a few miRs in the liver MNCs. Gene ontology analysis of the targets of miRs suggested that Toll-like receptor (TLR) signaling was among the most significantly targeted cellular pathways. Among the altered miRs, miR-145 was found to be the most significantly decreased. This finding correlated with concurrent upregulated expression of its predicted target gene, interleukin-1 receptor-associated kinase 3, a negative regulator of TLR4 signaling. Together, these data are the first to demonstrate that CB2 activation attenuates GalN/LPS-induced ALF by inducing an M1 to M2 shift in macrophages and by regulating the expression of unique miRs that target key molecules involved in the TLR4 pathway.

Introduction

Acute liver failure (ALF) is a highly devastating and potentially fatal syndrome caused by a sudden destruction of hepatocytes (Lee, 2012). Etiologies associated with ALF include drug overdose, viral hepatitis, and bacterial toxins (Zhan et al., 2014). The prognosis for ALF is very poor, and the syndrome is usually associated with a high mortality of up to 80% (Bernal et al., 2010). There is a definite need for the development of new and effective therapeutic strategies for the treatment of this syndrome (Mas and Rodes, 1997; Neuberger, 2005).

dx.doi.org/10.1124/jpet.114.220368.

In situ, a combination of d-galactosamine (GalN) and lipopolysaccharide (LPS) causes acute liver failure in animals, which closely resembles the immunologic and metabolic dysfunctions seen in the clinical syndrome (Rahman and Hodgson, 2000). Thus, GalN/LPS-induced ALF has been widely used as an animal model to study the pathogenesis of ALF and to develop new therapeutic strategies against it (Tunon et al., 2009). The model triggers ALF through the binding of LPS to Toll-like receptor 4 (TLR4) on liver resident macrophages, the Kupffer cells (KCs), leading to their activation and secretion of a number of proinflammatory cytokines (Zhan et al., 2014). These cytokines provide a signal for the ensuing massive infiltration of immune cells in the liver and initiation of apoptosis in the liver parenchyma, ultimately leading to ALF (Liang et al., 2014).

The cannabinoid (CB) system comprises the cannabinoid receptors, their ligands, and the proteins that mediate their synthesis and degradation (Mallat and Lotersztajn, 2008). The ligands include both endogenous lipidic signaling molecules and exogenous cannabinoids derived from Cannabis sativa or

Materials and Methods

Mice. Female C57BL/6 mice (8–10 weeks old) were purchased from the National Cancer Institute (Frederick, MD). Mice were housed and maintained under specific pathogen-free conditions at the Association for Assessment and Accreditation of Laboratory Animal Care–accredited animal facility of the School of Medicine at the University of South Carolina. All animal procedures were performed according to National Institutes of Health guidelines, and the protocols were preapproved by the Institutional Animal Care and Use Committee of the University of South Carolina.

Induction of Acute Liver Failure and Treatment with JWH-133 Compound. GalN and LPS (Sigma-Aldrich, St. Louis, MO) were dissolved in phosphate-buffered saline (PBS). JWH-133 was obtained from the National Institute on Drug Abuse (Rockville, MD). To induce ALF, mice were injected intraperitoneally with a combination of GalN and LPS at doses of 400 mg/kg and 5 μg/kg body weight, respectively (n = 10–12 in each group). PBS was used as vehicle (veh) for these experiments. JWH-133, obtained at an initial concentration of 5 mg/ml in 100% ethanol, was concentrated to 40 mg/ml using a speed vacuum system and diluted further in PBS for treatments. For treatment with JWH-133, mice were treated with two doses of 20 mg/kg each: the first dose was administered 24 hours before the GalN/LPS injection, and the second, 2 hours before the GalN/LPS injection. Blood samples were collected at 12 hours after GalN/LPS injection by retro-orbital bleeding, and sera were separated and stored at −80°C until further use. The survival of mice was observed for 12 hours after GalN/LPS injection. At 12 hours, mice were sacrificed and liver tissues were harvested for histology and isolation of mononuclear cells. The liver tissues were frozen and stored at −80°C until further use. All mice were carefully monitored, and any moribund mice were immediately euthanized.

Serum Cytokine Analysis and Alanine Transaminase Activity Assay. Sera samples collected 12 hours after GalN/LPS injections were analyzed for levels of cytokines (tumor necrosis factor α (TNF-α), IL-6, and monocyte chemotactic protein-1 (MCP-1)) (BioLegend, San Diego, CA) and to measure liver enzyme alanine transaminase (ALT) levels (Pointe Scientific, Canton, MI) as described earlier (Hegde et al., 2011).

Liver Histology. Liver tissues isolated at 12 hours after GalN/LPS injection were rinsed gently with PBS and fixed in 10% neutral buffered formalin for 24 hours, paraffin embedded, and sectioned using microtome to obtain 5-μm-thick sections. The sections were stained with H&E and examined under light microscopy to evaluate tissues for histopathological damage.

Isolation of Liver Mononuclear Cells. The liver-infiltrating cells were isolated using a modification of a protocol described earlier (Dong et al., 2004). In brief, livers were perfused with liver perfusion medium, cut into small pieces, and digested using liver digestion medium (Gibco/Life Technologies, Grand Island, NY). The digestion medium consisted of collagenase and dispase. Liver tissues were digested until single-cell suspension was obtained. The obtained suspension was filtered through a 100-μm nylon mesh filter and centrifuged. The resulting cell suspension was washed twice with PBS, and the mononuclear cells (MNCs) were isolated using Ficoll-Paque Plus (GE Healthcare Life Sciences, Pittsburgh, PA) density gradient centrifugation. MNCs were then filtered using a 70-μm nylon mesh filter and counted.

RNA Isolation, miRNA Microarray, Pathway Analysis, and Real-Time Polymerase Chain Reaction. RNA was isolated from liver MNCs using an miRNeasy kit (Qiagen, Valencia, CA). Total RNA isolated from two biologic duplicate samples of liver MNCs from both the LPS–vehicle group and LPS–JWH-133 group was analyzed using the Affymetrix GeneChip miRNA 3.0 array platform, according to the manufacturer's instructions (Affymetrix, Santa Clara, CA). Using Ingenuity Pathway Analysis (IPA) software (Qiagen, Redwood City, CA), the results from the miRNA microarray were analyzed to identify the gene ontologies associated with molecular pathways potentially altered by single or multiple miRNA target genes. The set of miRNAs that had greater than an average 1.5-fold linear fold difference between treatment versus vehicle groups were analyzed within immunologically relevant pathways in the database to identify target genes for each of these miRNAs. The list of targets was then uploaded to Cytoscape using the ClueGo plugin for gene ontology analysis (Bindea et al., 2009). Gene ontology analysis of immunologically relevant pathways was then performed for the pathways having P values <0.05 with right-sided hypergeometric enrichment and Benjamini-Hochberg false discovery rate testing. The
TLR pathway, as regulated by identified miRNAs, was generated using the IPA software. Quantitative real-time polymerase chain reaction (qRT-PCR) was performed to quantify the levels of miRNAs using miScript SYBR Green PCR kits and the following primer assays (Qiagen, Valencia, CA): mmu-miR-145 and Snord61. Snord61 was used as the reference gene for qRT-PCR.

**Immunoblotting.** Total protein was isolated from the peritoneal cavity of mice, washed with PBS, and evaluated for 24 hours. Macrophages were then treated with vehicle (0.05% dimethyl-sulfoxide) or JWH-133 (25 or 5 μM). One hour later, cells were treated with LPS (100 ng/ml). For macrophage polarization studies, cells were pretreated with 5 μM JWH-133 for 1 hour and then stimulated with either LPS (150 μM/ml) for 6 hours and then with LPS (10 mg/ml) for 1 hour or with IL-4 (20 μM/ml) for 2 hour polarization. Total protein was isolated from macrophages 6 hours after LPS or IL-4 stimulation. Cell culture supernatants were isolated 24 hours later for enzyme-linked immunosorbent assay to quantify TNF-α, IL-12, and IL-10 secretion by macrophages.

**Statistical Analysis.** For the experiments, 10–12 mice were used per experimental group. For in vivo assays and qRT-PCRs, all experiments were performed in triplicate. For statistical differences, one-way analysis of variance was used to analyze significance for each experiment, and Tukey’s post-hoc test was performed to analyze differences between the groups. Results are shown as the average ± S.E.M. wherever applicable. A P value <0.05 was used to determine statistical significance. Single and double asterisks represent significant differences with P values <0.05 and <0.01, respectively. The graphs were plotted using GraphPad Prism (GraphPad Software, La Jolla, CA), and the densitometric analysis was performed using ImageJ software (NIH, Bethesda, MD).

**Results**

**Attenuation of ALF in JWH-133-Treated Mice.** We first investigated if treatment of mice with the CB2 agonist JWH-133 can protect mice from GalN/LPS-induced ALF. To this end, we treated the mice with JWH-133 at a dose of 20 mg/kg body weight. This dose was based on the results of our pilot studies and other published studies, we determined that doses of 25 and 5 μM suppressed LPS-induced activation and were noncytotoxic to macrophages over 24-hour cultures. Therefore, we used these doses of JWH-133 for pretreatment of peritoneal macrophages 1 hour prior to LPS stimulation. We observed that JWH-133 treatment completely suppressed caspase-3 cleavage in the liver tissues, suggesting protection of liver from tissue apoptosis.

**JWH-133 Treatment Decreases Liver Infiltration of MNCs, Production of Proinflammatory Cytokines, and Liver Apoptosis upon GalN/LPS Injection.** Based on the marked reduction of infiltration of immune cells in the liver tissues, we next quantified the differences in liver infiltration of immune cells. To this end, we isolated the liver mononuclear cells from the livers of the different groups of mice. Mice with GalNLPS+vehicle-induced ALF showed a significant increase in numbers of MNCs that infiltrated the liver, whereas mice that received treatment with GalNLPS+JWH-133 had a significantly lower number of MNCs in the liver tissues (Fig. 2A).

We next investigated the production of proinflammatory cytokines in different groups of mice by quantifying the serum levels of TNF-α, MCP-1, and IL-10 for 12 hours after injecting mice with GalNLPS. We observed a significant increase in the levels of all of these proinflammatory cytokines in mice that had ALF post-GalNLPS+vehicle injection. We also noted a significant decrease in the serum levels of these proinflammatory cytokines in the mice that received GalNLPS+JWH-133 treatment (Fig. 2B). Because hepatocyte apoptosis is the major event that leads to ALF (Liang et al., 2014), and caspase-3 is a major mediator of apoptosis, we next studied the effect of JWH-133 upon the GalNLPS+vehicle-triggered apoptosis in liver tissue by immunoblotting. Liver tissues isolated from mice 12 hours after GalNLPS+vehicle injection showed a very significant increase in caspase-3 cleavage indicative of liver tissue damage by apoptosis (Fig. 2C). In contrast, GalNLPS+JWH-133 treatment completely suppressed caspase-3 cleavage in the liver tissues, suggesting protection of liver from tissue apoptosis.

**JWH-133 Treatment Suppresses the LPS-Induced Activation Macrophages and Triggers an M1 to M2 Phenotype Shift in Macrophage Polarization In Vitro.** Because macrophages play an important role in the pathogenesis of GalNLPS-induced ALF, we investigated the effects of JWH-133 on macrophages in vitro, specifically to produce proinflammatory cytokines upon LPS activation. Based on our pilot studies and other published studies, we determined that doses of 25 and 5 μM suppressed LPS-induced activation and were noncytotoxic to macrophages over 24-hour cultures. Therefore, we used these doses of JWH-133 for pretreatment of peritoneal macrophages 1 hour prior to LPS stimulation. We observed that JWH-133 treatment caused a significant suppression in the production of proinflammatory cytokines, including TNF-α and IL-12, whereas it increased the production of the anti-inflammatory cytokine IL-10 (Fig. 3A).

Because a switch from M1 to M2 macrophage phenotype leads to suppression of inflammation, we next determined if JWH-133 used this mechanism to suppress ALF. To this end, we pretreated peritoneal macrophages with JWH-133 and then stimulated the cells, polarizing them toward M1 or M2 phenotype, and the culture supernatants were analyzed for TNF-α, IL-12 (indicative of M1), and IL-10 (indicative of M2). Interestingly, our data showed that JWH-133 increased the production of the anti-inflammatory cytokine IL-10 (Fig. 3A).
increase in the expression of these M2 phenotype–associated markers. More importantly, JWH-133 caused a significant additional increase in the expression of both Arg-1 and Chi3l3 (Fig. 3, C and D). These results suggested that JWH-133 suppresses M1 activation while potentiating M2 phenotype.

**JWH-133 Treatment of GalN/LPS-Injected Mice Increases M2 Macrophage Phenotype Polarization in Liver.** To corroborate if the M1 to M2 switch can be seen in vivo, we investigated the effect of JWH-133 treatment on the expression of M1 and M2 macrophage phenotypic markers in liver MNCs isolated 12 hours after GalN/LPS injections by qRT-PCR. We observed that expression of the typical M1 phenotype markers, TNF-α and nitric oxide synthase 2 (Nos2), was significantly increased in mice with GalN/LPS+vehicle, whereas GalN/LPS+JWH-133 treatment significantly suppressed this expression (Fig. 4A). On the other hand, expression of the typical M2 markers, Arg-1 and IL-10, was increased upon JWH-133 treatment (Fig. 4B). Together, these results suggested that JWH-133 may ameliorate LPS-induced ALF, at least in part, by promoting M1 to M2 switch in macrophage phenotype in the liver.

**JWH-133 Treatment of GalN/LPS-Injected Mice Significantly Alters the miRNA Profile of Liver MNCs.** Because GalN/LPS-induced ALF results from acute inflammation, which is also regulated by microRNAs, we next investigated their role in the current model. For this purpose, we investigated the change in expression of miRNAs in response to JWH-133 treatment of mice exposed to GalN/LPS. To this end, we performed microarray analysis for the expression of 2023 miRNAs in the liver MNCs of GalN/LPS+JWH-133–treated
mice versus those that received GalN/LPS+vehicle. JWH-133 treatment caused a significant change in the miRNA expression profile of liver MNCs, as seen in the heat map (Fig. 5A).

We also investigated the gene ontologies associated with the cellular pathways potentially changed by using IPA software, and determined the miRNAs with more than 1.5-fold change in the GalN/LPS+JWH-133 group when compared with the GalN/LPS+vehicle group. Next, immunologically relevant target genes for such miRNAs were identified using IPA. Gene ontology analysis of these target genes revealed a number of pathways most affected by the target genes altered in the GalN/LPS+JWH-133–treated mice when compared with the GalN/LPS–treated mice. Here, we observed that TLR signaling was one of the most affected ontologies pertinent to macrophage function as well as regulation of macrophage differentiation (Fig. 5, B–D). These pathways were strongly predicted to suppress the expression of various negative regulators of the TLR4 signaling pathway, as shown in the pathway analysis.

**JWH-133 Treatment Decreases Expression of miR-145 to Regulate Interleukin-1 Receptor–Associated Kinase 3 and Modulate TLR4 Signaling.** Our analysis led us to identify a relatively small number of miRNAs that were significantly altered in GalN/LPS+JWH-133–treated mice when compared with GalN/LPS–treated mice (Fig. 6A). Among these, miR-145 emerged as the most significantly altered miRNA, with a 5-fold decrease in the mice treated with JWH-133. Next, we used the miRWalk database (Dweep et al., 2011), a powerful tool that can predict miRNA–target gene interactions to identify predicted targets most relevant to TLR4 signaling. One such strongly predicted miRNA–gene interaction that caught our attention was miR-145-5p to the 3′-untranslated region of the interleukin-1
receptor–associated kinase 3 (IRAK3) mRNA (Fig. 6B). In addition to miRWalk-based predicted binding between miR-145 and IRAK3, we also used the miRanda algorithm to verify the predicted interaction between the two sequences. This analysis also suggested a strong interaction between miR-145 and its predicted target, IRAK3, based on the mirSVR score (Fig. 6C).

IRAK3 is a member of the IRAK family and, unlike other IRAK family members, has been shown to negatively regulate the downstream signaling from the stimulated TLRs. Thus, next we validated the expression of miR-145 in liver MNCs isolated at 12 hours post-GalN/LPS vehicle treatment using qRT-PCR. Whereas the expression of miR-145 was increased by about 3-fold in mice with GalN/LPS vehicle-induced ALF, mice with GalN/LPS JWH-133 treatment indeed showed decreased expression of miR-145 when compared with the mice with LPS-induced ALF (Fig. 6D). Concurrently, the expression of IRAK3, the predicted target gene of miR-145, on the other hand, was found to be increased in mice treated with GalN/LPS + JWH-133 when compared with mice with GalN/ LPS-induced ALF (Fig. 6E). These results taken together demonstrate that JWH-133 can suppress GalN/LPS-induced ALF through changes in macrophage polarization and miRNA expression modulation to tame the TLR4 signaling in response to LPS-induced inflammatory response.

Discussion

Acute liver failure represents the most destructive form of liver damage (Lee, 2012). Considering the substantial evidence underscoring the roles of systemic inflammatory response syndrome, multiple organ dysfunction syndrome, and sepsis in the progression of ALF (Antoniades et al., 2008), a therapeutic agent for ALF could also represent good promise against these similar types of inflammatory disorders. Several studies have underlined the significance of LPS in pathogenesis of both chronic and acute liver pathologies, including ALF (Nolan, 2010; Zhan et al., 2014), which further strengthens the clinical relevance of the GalN/LPS-induced ALF animal model.

CB2 receptor activation has been previously shown to mediate anti-inflammatory effects in liver injury (Munoz-Luque et al., 2008; Louvet et al., 2011). However, the role of microRNAs in such models of protection has not been previously investigated. In the current study, we demonstrated that treatment with a select CB2 agonist, JWH-133, protected the mice from GalN/LPS-induced ALF, based on increased survival, decreased serum ALT levels, decreased number of liver-infiltrating MNCs, and reduced histologic damage to the liver. The effectiveness of JWH-133 was remarkable in this acute liver injury model inasmuch as 100% of such mice survived the GalN/ LPS challenge. JWH-133 treatment significantly upregulated the expression of markers for anti-inflammatory macrophage...
Recent studies have shown that in vitro CB2 activation induced activation of liver resident macrophages. Indeed, attenuation of ALF could be the suppression of the LPS-protective action of mice from LPS-induced ALF.

Activation in liver tissues, suggesting CB2-mediated pro-inflammatory and significantly reduced the apoptosis mediated by caspase-3 treatment also decreased the infiltration of MNCs in the liver chemokines that were induced by LPS. In addition, JWH-133 treatment also decreased the infiltration of MNCs, to repress the LPS-induced TLR4 pathway.

Insights from recent studies have led us to identify different functional subsets of macrophages, two main phenotypes being M1 and M2. M1 macrophages are associated with cytotoxic and proinflammatory functions, whereas M2 macrophages have anti-inflammatory and tissue injury–resolving functions (Sica and Mantovani, 2012). In our current study, we observed that JWH-133 treatment increased the secretion of IL-10, a typical M2 phenotype marker in macrophages that had been stimulated toward M1 phenotype by using IFN-β+LPS. Interestingly, the CB2 agonist also enhanced the expression of other typical M2 phenotype markers, Arg1 and Chil3, suggesting that CB2 activation not only causes an M1 to M2 shift in M1-stimulated macrophages but also potentiates stimulation to the anti-inflammatory M2 macrophage phenotype. IL-10 is an anti-inflammatory cytokine that has been shown to be hepatoprotective in the GalN/LPS-induced ALF model (Santucci et al., 1996).

For our in vitro study, we chose to use doses of 5 and 25 μM JWH-133 1 hour prior to LPS activation of macrophages. These doses of JWH-133 to activate CB2 receptors on the macrophages are similar to what have been published earlier in the in vitro studies, showing its protective effects against different liver pathologies (Teixeira-Clerc et al., 2010; Louvet et al., 2011). One can also question if, at these concentrations of JWH-133, the compound is acting through CB1 receptors due to some cross-reactivity. We believe that this is unlikely because the reported expression of the CB1 receptor on the inflammatory macrophages/monocytes is up to 100 times lower than that of the CB2 receptor (Pacher et al., 2006; Han et al., 2009), which makes it much more likely that the protective effects of JWH-133 are mediated through a specific activation of the CB2 receptor. Nevertheless, a partial CB1 activation cannot be definitively ruled out at this point.

Although we focused our current study on macrophages, one can reason that JWH-133 could be acting on other cells in the liver as well. Although this possibility cannot be ruled out entirely, we reason that this is less likely based on the previous findings that the CB receptors, particularly CB2, are expressed at low levels or even absent in healthy liver tissues (Pacher et al., 2006; Floreani et al., 2010). Furthermore, to our knowledge, there are no reports to suggest an increase in liver pathologies in humans or animals.

A switch in KCs to the M2 phenotype has been shown to be protective against liver pathologies, such as alcoholic liver disease (Louvet et al., 2011) and obesity-induced insulin resistance (Odegaard et al., 2008). Thus, based on our in vitro findings, we investigated the effect of JWH-133 treatment on the expression of typical M1 and M2 markers in mice with LPS-induced ALF. We noticed an increase in the expression of M1 markers, TNF-α and Nos2, in the liver MNCs of ALF-induced mice, whereas the CB2 agonist decreased the secretions of proinflammatory cytokines by decreasing the secretion of proinflammatory cytokines (Louvet et al., 2011). In the present study, we also observed that JWH-133 treatment of macrophages decreased the secretion of proinflammatory cytokines, such as TNF-α and IL-12 in response to LPS stimulation, and increased the secretion of the anti-inflammatory cytokine IL-10.

Fig. 4. JWH-133 treatment induces in vivo M2 polarization of macrophages in mice with LPS-induced ALF. Liver MNCs were isolated for the different groups of animals treated with vehicle (Veh) alone, JWH-133 alone, LPS+Veh, or LPS+JWH-133 at 12 hours after GalN/LPS injection. Relative expression of typical M1 markers, TNF-α and Nos2 (A), and typical M2 markers, Arg-1 and IL-10 (B), in liver MNCs as quantified by qRT-PCR is shown. *P < 0.05; **P < 0.01.
expression of these markers. It is worthy to note here that TNF-α is the most important mediator that triggers hepatocyte apoptosis in LPS-induced ALF (Leist et al., 1995; Nowak et al., 2000), and JWH-133 treatment of mice was able to decrease both systemic serum levels and liver-specific expression of TNF-α. Nos2 has also been identified as one of the major mediators of inflammation, both in clinical ALF (Leifeld et al., 2002) and in GalN/LPS-induced ALF (Sass et al., 2001). Thus, the ability of JWH-133 to suppress liver-specific expression of Nos2 in mice with LPS-induced ALF is
compelling. Even more interestingly, we observed that JWH-133 treatment increased the expression of typical M2 markers, Arg-1 and IL-10, within the liver MNCs. These results together suggested that CB2 activation induces an M1 to M2 shift within the liver resident macrophages in mice with LPS-induced ALF.

TLR4 activation by LPS initiates a signal transduction pathway involving MyD88 recruitment to TLR4, leading to nuclear translocation of nuclear factor κB, which promotes the transcription of various proinflammatory genes (Lu et al., 2008). Recent studies have suggested that miRNAs play an important role in the regulation of TLR responses (O’Neill...
Thus, we next investigated if JWH-133–induced miRNA changes were a potential mechanism by which the CB2 agonist was able to suppress LPS-induced ALF. In our present study, we found that JWH-133 treatment significantly decreased the expression of miR-145 in liver MNCs. Furthermore, we identified a number of immunologically relevant gene ontologies that were predicted to be targeted by the changes in miR expression among the JWH-133–treated mice. In particular, we showed that the changes in miRs could potentially regulate the expression of a number of genes involved in macrophage function and differentiation, including regulation of TLR4 signaling in response to TLR ligands, such as LPS. Our in silico analysis showed that IRAK3, previously shown to inhibit LPS-induced TLR4 activation (Kobayashi et al., 2002), was a highly predicted target gene that could be suppressed by miR-145. This suggests that

---

**Fig. 6.** JWH-133 treatment suppresses TLR signaling in liver MNCs by decreasing the expression of miR-145 to regulate IRAK3. (A) Table of miRNAs significantly increased or decreased by more than 1.5-fold change in LPS+JWH-133–treated mice when compared with LPS+vehicle (Veh)-treated mice. (B) Toll-like receptor pathway showing the predicted interaction between miR-145, the most significantly altered miRNAs in the LPS+JWH-133 group with its predicted target IRAK3 (shown in blue), and how they relate to the rest of the members of the pathway. (C) miRanda algorithm generated miR-145 and mRNA alignment at the 3′-untranslated region of IRAK3 mRNA. mirSVR and PhastCons conservation scores are also shown. miR-145 (D) and its predicted target IRAK3 in liver MNCs (E), as quantified by qRT-PCR at 12 hours after GalN/LPS injection. *P < 0.05; **P < 0.01. CYLD, cylindromatosis (turban tumor syndrome); IKK, inhibitor of κ light polypeptide gene enhancer in B cells, kinase β; MAPK, mitogen-activated protein kinase; NF-κB, nuclear factor κB; PPARα, peroxisome proliferator-activated receptor α; TIRAP, Toll-interleukin 1 receptor (TIR) domain containing adaptor protein.
induction of IRAK3 expression could be a useful strategy to dampen the LPS-induced TLR4 responses and hence attenuate LPS-induced ALF pathogenesis. Therefore, we validated our findings from in silico analyses and found an increase in IRAK3 expression in liver MNCs from GalN/LPS + JWH-133–treated mice relative to GalN/LPS + vehicle–treated mice, along with a concurrent decrease in the expression of miR-145, thus suggesting that miR-145–led increase in IRAK3 may be a potential mechanism of action by which JWH-133 suppresses LPS-induced ALF.

In summary, we demonstrate that JWH-133, a CB2 agonist, can protect mice from liver injury triggered by inflammation. Our findings are significant inasmuch as this represents the first finding of attenuation of LPS-triggered TLR4 signaling by JWH-133 through a negative feedback involving changes in expression of distinct miRNAs to regulate critical regulators of TLR4 signaling, such as IRAK3.
