Abstract

The present study investigated the serotonin-induced increase in phosphoinositide hydrolysis and mobilization of intracellular Ca^{2+} ([Ca^{2+}]_i) in human uterine smooth muscle cells (HUSMC) in order to identify the serotonergic receptor positively coupled to phospholipase C in these cells. In PI assays, 5-HT and α-methyl-5-HT were potent, full agonists (EC_{50} = 20 and 4.1 nM, respectively) while the phenylethylamine, R-DOI was less active (EC_{50} = 63 nM). Proposed 5-HT_{2B} selective agonists, BW-723C86 and (+)-norfenfluramine exhibited strong agonist potency and efficacy comparable to 5-HT (EC_{50} = 18 and 33 nM, respectively) and ~15-fold more potent than (-)-norfenfluramine (EC_{50} = 500 nM). 5-HT_{2C} receptor agonists mCPP and MK-212, were weak agonists in these cells with potencies of 110 and 880 nM, respectively. A similar rank order of potency was observed in [Ca^{2+}]_i mobilization assays (r = 0.9, p < 0.005) in the HUSMC and with contraction of rat stomach fundus strips that contain a 5-HT_{2B} receptor (r = 0.9, p < 0.001). Antagonist studies revealed that a 5-HT_{2B}-selective antagonist, RS-127445 (K_i = 0.13 nM), was significantly more effective at inhibiting 5-HT-induced activity than a 5-HT_{2A} antagonist, M-100907 (K_i = 914 nM) and the 5-HT_{2C} antagonists RS-102221 (K_i = 2.5μM) and SB-242084 (K_i = 42.4 nM) in the HUSMC PI turnover assays. Taken together, these studies strongly suggest the presence of a functionally active 5-HT_{2B} receptor subtype in HUSMC. The physiological role of this receptor in these cells remains to be defined.
Introduction

Serotonin (5-hydroxytryptamine, 5-HT) is known to exert a wide variety of physiological actions through its interaction with an extensive family of 5-HT cell-surface receptors (Hoyer et al., 1994; 2002). In particular, the 5-HT$_2$ receptor family comprises three subtypes, 5-HT$_{2A}$, 5-HT$_{2B}$, and 5-HT$_{2C}$, which have been reported to play a major role in a host of central nervous system functions including anxiety, depression, migraine, obesity, and schizophrenia. Due to the involvement of 5-HT$_2$ receptor signaling in these disorders, there has been an increased interest in the therapeutic potential of selective 5-HT$_2$ ligands as antidepressants, anti-obesity drugs, and anxiolytic agents (Hoyer et al., 1994; 2002).

Further studies have identified serotonin in human aqueous humor (Veglio et al., 1998) and functionally coupled 5-HT$_2$ receptors in rat retinal pigment epithelial cells (Osborne et al., 1993) and bovine ciliary epithelium (Inoue-Matsuhisa et al., 2003). These findings suggested a possible role of serotonin and its receptors in aqueous humor dynamics and as a possible target for ocular pathologies. Indeed, it has recently been shown that topical ocular administration of 5-HT$_2$ receptor agonists effectively lowered intraocular pressure in a nonhuman primate model of laser-induced ocular hypertension (May et al., 2003) suggesting a potential utility of 5-HT$_2$ agonists as anti-glaucoma therapeutics. However, the current lack of subtype selective ligands, especially agonists, has made it difficult to ascribe the hypotensive action of these molecules to an individual 5-HT$_2$ receptor subtype.

Recently, the appetite suppressant fenfluramine was withdrawn from the US market due to its association with valvular heart disease (Connolly et al., 1997).
Norfenfluramine, the active metabolite of fenfluramine, has been implicated as the causative agent in the observed valvular hyperplasia due to its apparent activity at the 5-HT$_{2B}$ receptor (Fitzgerald et al., 2000) though other biological activities of norfenfluramine have not been ruled out. Because of the potential for unwanted side effects using nonselective agonists, there is great interest in developing 5-HT$_2$ receptor subtype specific therapeutics that are devoid of 5-HT$_{2B}$ receptor agonist activity.

We sought to identify cell systems endogenously expressing human 5-HT$_2$ receptor subtypes in order to characterize compounds of interest at these therapeutically important receptors. Although compound characterization using cell types with endogenous receptors can be confounded by competing activities at other receptor types, the resulting pharmacology at physiological expression levels and with the native G-protein coupling system may give a more relevant profile than the use of cell lines over-expressing receptors and/or promiscuous G-protein systems. The 5-HT$_2$ receptor subtypes are implicated in serotonin-induced smooth muscle contraction and resulting constriction presumably through G$_q$-coupled activation of phospholipase C, phosphoinositide (PI) hydrolysis and intracellular calcium mobilization. For example, 5-HT$_{2A}$ receptors have been identified in vascular smooth muscle tissue and cells where activation of 2A receptors induces tissue contraction and vasoconstriction. 5-HT$_{2B}$ receptors are highly expressed in rat stomach fundus and contraction of rat fundic strips is a prototypic assay used to characterize functional agonist activity of compounds at the 5HT$_{2B}$ receptor (Baxter et al., 1994). We tested commercially available cell lines for PI metabolism in response to 5-HT and other prototypic serotonergic compounds. Through our search, we discovered that 5-HT and other agonists induced a reproducible PI
turnover response and mobilized intracellular calcium in a human uterine smooth muscle cell type (HUSMC). In this study, we describe the pharmacological profile of the 5-HT₂ receptor present in HUSMC using prototypic serotonergic agonists and reported subtype-selective 5-HT₂ receptor antagonists.
Methods

Materials / Chemicals

5-hydroxytryptamine hydrochloride; α-methyl-5-hydroxytryptamine maleate; R-(-)-1-(4-iodo-2,5-dimethoxyphenyl)-2-aminopropane hydrochloride (R-DOI) and other reagents were purchased from Sigma/RBI (Natick, MA). 6-chloro-2-(1-piperaxinyl)pyrazine (MK212); m-chlorophenylpiperazine (m-CPP); α-methyl-5-(2-thienylmethoxy)-1H-indole-3-ethanamine hydrochloride (BW-723C86) and 8-[5-(2,4-dimethoxy-5-(4-trifluoromethylsulfo-amido)phenyl-5-oxopentyl]-1,3,8-triazaspiro[4.5]decane-2,4-dione hydrochloride (RS-102221) were obtained from Tocris Cookson Inc. (Ellisville, MO) R-(+)-α-(2,3-dimethoxyphenyl)-1-[2-(4-fluorophenyl)ethyl]-4-piperidinemethanol (M100907); 6-chloro-5-methyl-1-[6-92-methylpyridin-3-yloxy) pyridine-3-ylcarbamoyl] indoline (SB-242084); 2-amino-4-(4-fluoronaphth-1-yl)-6-isopropylpyrimidine (RS-127445); R-norfenfluramine and S-norfenfluramine were synthesized by the Medicinal Chemistry department of Alcon Research, Ltd or external contract. [3H]-myoinositol (18.5 Ci/mmol) was purchased from PerkinElmer Life Sciences (Boston, MA). Formic acid, ammonium formate, and LiCl were obtained from Sigma Chemical (St. Louis, MO); AG-1X8 anion-exchange resin and columns were from Bio-Rad (Hercules, CA). Ecolume scintillation cocktail was obtained from ICN Biomedicals (Costa Mesa, CA). Fluorometric imaging plate reader (FLIPR) and calcium assay kit dyes were from Molecular Devices Corp. (Sunnyvale, CA).

Cell Culture
Human uterine smooth muscle cells (HUSMCs), catalog #CC-2562, were obtained from Cambrex (Walkersville, MD). Cell culture media, antibiotics, and trypsin-EDTA were purchased from Invitrogen (Carlsbad, CA). Fetal bovine serum was obtained from Hyclone Laboratories (Logan, UT), heat-inactivated at 56ºC for 30 min and stored at -20ºC. HUSMCs were cultured in Dulbecco’s modified Eagle’s medium (DMEM) containing 4.5 g/l glucose, 110 mg/l sodium pyruvate, pyridoxine hydrochloride, and GlutaMax I, supplemented with 10% fetal bovine serum and 10µg/ml gentamicin sulfate.

In Vitro Functional Assays

Phosphoinositide Hydrolysis Assay

Phosphoinositide hydrolysis (PI turnover) assays of phospholipase C activity were conducted by measurement of the agonist-stimulated production of [3H]-inositol phosphates from [3H]-myoinositol as previously described (Sharif and Xu, 1996; Griffin et al., 1998). Briefly, confluent monolayers of human uterine smooth muscle cells were exposed for 24 - 30 hours to 1 - 1.5 μCi of [3H]-myoinositol (18.5 Ci/mmol) in 0.5 mL of serum-free media to label cell membrane phospholipids. Cells were rinsed once with DMEM/Ham’s F12 containing 10 mM LiCl before incubation with agonist for 1 hour at 37ºC.

For antagonist experiments, the selected antagonist was preincubated with cells for 15 minutes prior to addition of agonist and continued incubation for 1 hour at 37ºC. The reaction was quenched by aspiration of the medium and addition of 1 mL cold 0.1 M formic acid to lyse the cells. Cell sample processing and separation of [3H]-inositol...
phosphates was achieved with anion-exchange chromatography. Cell lysates were loaded onto columns containing AG-1X8 anion-exchange resin. Unincorporated [³H]-myoinositol was removed by sequential washing with water and 50 mM ammonium formate. Total [³H]-inositol phosphates fraction was eluted from the columns with 1.2 M ammonium formate containing 0.1 M formic acid. The eluate was collected and mixed with 15 mL scintillation cocktail and the total [³H]-inositol phosphates was determined by liquid scintillation counting on a beta counter at ~50% efficiency (LS6000; Beckman Instruments, Carlsbad, CA). Apparent inhibition constants (Kₐ) values for the functional antagonist experiments using phosphoinositide hydrolysis were calculated from the determined 50% inhibition concentrations (IC₅₀) as described elsewhere (Cheng and Prusoff, 1973).

**Intracellular Calcium Mobilization Assay**

Intracellular calcium mobilization [Ca²⁺]ᵢ induced by 5-HT and other serotonergic compounds in HUSMCs was studied using a Fluorescence Imaging Plate Reader (FLIPR) instrument (Molecular Devices, Sunnyvale, CA)(Schroeder and Neagle, 1996). Evaluation of the functional agonist activity of test compounds was performed using a protocol previously described (Kelly et al., 2003; May et al., 2003). Briefly, confluent cell monolayers of human uterine smooth muscle cells were trypsinized, pelleted, and seeded at a density of 20,000 cells per well in black-walled, 96-well tissue culture plates and grown to confluency. The fluorescence response of HUSMCs was enhanced by growing the cells in medium containing 10% dialyzed FBS for 2 - 3 days followed by incubation in serum-free medium overnight prior to the experiment. For the experiment,
cells were loaded with a calcium sensitive fluorescent dye provided in a calcium assay kit (Molecular Devices). The dye was reconstituted in FLIPR buffer [Hanks’ balanced salt solution buffered with 20 mM Hepes, pH 7.4, 2.5 mM probenecid] and incubated with cells at 23 ºC for 1 hr. Test compounds were diluted in 25% dimethyl sulfoxide / 25% ethanol and further dilutions were prepared in FLIPR buffer and evaluated in concentration response formats. Agonist-stimulated intracellular calcium mobilization was measured on a FLIPR I system monitoring real-time changes in cellular fluorescence ($\lambda_{ex} = 488$ nm, $\lambda_{em} = 540$ nm) upon agonist additions. Calibration of the instrument was performed using manufacturer’s standard procedures.
Results

Phosphoinositide Hydrolysis Agonist Studies

In phosphoinositide hydrolysis (PI turnover) experiments using [3H]-myoinositol, treatment of human uterine smooth muscle cell (HUSMC) monolayers with 5-HT and other prototypic serotonergic compounds consistently resulted in a production of [3H]-inositol phosphates. This agonist-stimulated generation of inositol phosphates suggested the presence of Gq-coupled 5-HT2 receptors in the HUSMC. In order to further characterize the 5-HT2 receptor subtype(s) responsible for the observed PI turnover, prototypic serotonergic agonists with some reported 5-HT2 receptor subtype selectivity were analyzed in concentration-response format using the PI turnover assay in HUSMC. 5-HT, nonselective, and reportedly subtype selective 5-HT2 agonists induced the activation of phospholipase C and subsequent inositol phosphate generation in a concentration-dependent manner (Figure 1A and B). Tested compounds were then compared and ranked based on the functional potencies determined from the concentration-response curves (Table 1). The nonselective natural ligand, 5-HT, was a potent, full agonist (EC50 = 20 ± 2.8 nM, Emax = 105 ± 6%) whereas α-methyl-5-HT exhibited approximately 5-fold stronger potency than 5-HT (EC50 = 4.1 ± 2.1 nM, Emax = 93 ± 12%) in the assay. The tryptamine analog BW-723C86, described as a 5-HT2B selective agonist, exhibited strong agonist potency and efficacy comparable to 5-HT (EC50 = 18 ± 2.5 nM, Emax = 104 ± 4%). The phenylethylamine ligand R-DOI, considered to be a relatively selective and potent 5-HT2A receptor agonist, was a full agonist with a modest potency weaker than 5-HT, α-methyl-5-HT and BW723C86. The piperazines mCPP and MK-212 exhibited functional potencies of 110 ± 32 nM and 880 ±
320 nM respectively, with mCPP consistently displaying partial agonist efficacy ($E_{max} = 37 \pm 5 \%$). MK-212 had the weakest potency of the compounds tested. The (+)- and (–)-isomers of norfenfluramine, the active metabolite of fenfluramine, were tested for agonist activity in PI turnover dose response. (+)-norfenfluramine displayed very good potency comparable to 5-HT and ~15-fold better than (–)-norfenfluramine (Figure 1B and Table 1).

**Intracellular Calcium Mobilization**

The human uterine smooth muscle cells were tested for mobilization of intracellular calcium in response to 5-HT and selected serotonergic agonists. As expected, 5-HT at 10µM elicited a rapid increase in relative fluorescence compared to basal fluorescence in HUSMCs indicative of increased intracellular calcium ([Ca$^{2+}$]$_i$) as monitored in real-time using the FLIPR instrument. Surprisingly, the relative fluorescence change measuring calcium mobilization in response to 5-HT and other serotonergic compounds was lower than anticipated based on the robust, consistent phosphoinositide metabolism response in these cells. It was also significantly lower than the 5-HT-induced fluorescence change observed with endogenous 5-HT$_2$ receptors of rat aortic smooth muscle (A7r5) cells (Doyle et al., 1986; May et al., 2003). The HUSMCs exhibited good viability and adequate loading of the calcium-sensitive dye based on a very robust fluorescence increase in response to 10µM histamine observed in these cells. The consistency and magnitude of the 5-HT-induced [Ca$^{2+}$]$_i$ mobilization was improved by growing the cells in media with 10% dialyzed serum for 2 -3 days and then overnight in serum-free medium prior to the experiment. All serotonergics tested induced increases in relative
fluorescence in HUSMC in a concentration-dependent manner (Figure 2; Figures 3A and 3B) and potency and efficacy values were determined from the generated curve fits (Table 2). The rank order potencies of the tested compounds were similar to those observed using PI hydrolysis as the functional readout. 5-HT and α-methyl 5-HT were the most potent agonists in the calcium assay. The potencies of BW-723C86 and (+)-norfenfluramine were weaker than observed in the PI experiments but comparable to the activity of R-DOI. MK212, mCPP, and (−)-norfenfluramine were weak agonists for calcium mobilization as they were for PI hydrolysis (EC\textsubscript{50} > 1 µM). mCPP showed partial agonist efficacy in the assay (E\textsubscript{max} = 54%).

**Phosphoinositide Hydrolysis Antagonist Studies**

To better characterize the 5-HT\textsubscript{2} receptor subtype responsible for PI hydrolysis in human uterine smooth muscle cells, we tested subtype-selective antagonists for the ability to inhibit the 5-HT-mediated PI metabolism. The agonist activity of a submaximal concentration of 5-HT (30 nM) was challenged using increasing concentrations of the selective 5-HT\textsubscript{2A} antagonist, M-100907, the 5-HT\textsubscript{2C} selective antagonists, SB-242084 and RS-102221, and the 5-HT\textsubscript{2B} selective antagonist, RS-127445. All 5-HT\textsubscript{2} receptor antagonists tested inhibited the 5-HT-induced PI hydrolysis in HUSMCs in a concentration-dependent fashion (Figure 4). However, there was greater than two orders of magnitude separation in potency between RS-127445 and the other antagonists tested. The 5-HT\textsubscript{2B} antagonist was by far the most potent inhibitor of the 5-HT agonist response, exhibiting a subnanomolar IC\textsubscript{50} (Figure 4). The IC\textsubscript{50} values derived from the antagonist concentration response studies were converted into apparent inhibition constant (K\textsubscript{i})
values using the Cheng-Prusoff equation (Cheng and Prusoff, 1973) (Table 3). The 5-HT$_{2C}$ receptor selective antagonists SB-242084 and RS-102221, were much less effective inhibitors in these cells producing apparent $K_i$ values approximately 400-fold and $>10,000$-fold weaker than the potency of RS-127445, respectively (Table 3). The potent 5-HT$_{2A}$ receptor antagonist, M-100907, was also a very weak inhibitor of the 5-HT response in this system, $K_i = 914$ nM, which was nearly 10,000-fold weaker than the potency of the 5-HT$_{2B}$ antagonist.

As mentioned above, the rank order potencies of serotonergic agonists were comparable using either PI hydrolysis or mobilization of intracellular calcium as the functional readout. A correlation plot of pEC$_{50}$ data for PI turnover (Table 1) against pEC$_{50}$ data for functional Ca$^{2+}$ mobilization (Table 2) shows a high level of agreement ($r = 0.9$, p< 0.005) between these two sets of data (Figure 5A). The [Ca$^{2+}$]$_i$ mobilization pEC$_{50}$ data from the current study in HUSMCs also correlated with previous FLIPR functional data using cloned human 5-HT$_{2B}$ receptors expressed in CHO-K1 cells, $r =0.84$, p<0.01 (Table 2 and Porter et al., 1999). The functional PI data (pEC$_{50}$; $pK_i$) obtained with selected agonists in HUSMCs in the present study correlated most strongly with the reported functional data (pEC$_{50}$; $pA_2$) for these same compounds inducing the 5-HT$_{2B}$-mediated contraction of rat stomach fundus tissues obtained by Baxter and coworkers, $r = 0.91$, p<0.001 (Table 1 and Figure 5B) (Baxter et al., 1994 and Baxter, 1996).
Discussion

Exposure of human uterine smooth muscle cells to 5-HT and other prototypic serotonergic compounds elicited production of [3H]-inositol phosphates in PI hydrolysis and triggered mobilization of intracellular calcium consistent with the presence of functional G_q-coupled 5-HT_2 receptors in these cells.

A panel of prototypic serotonergic agonists with reported selectivity at the various 5-HT_2 receptor subtypes was profiled using PI turnover and [Ca^{2+}]_i mobilization assays in HUSMC. There is a paucity of available 5-HT_2 subtype-selective agonists and the compounds reported in the literature to exhibit selectivity give conflicting results in diverse assay systems. Selectivity is further complicated by observed species-dependent differences in agonist activity (Wainscott et al., 1996). However, the strong potency of reported 2B selective agonists and the rank order profile of agonists from our results suggested a 5-HT_2B receptor was present in human uterine smooth muscle cells.

5-HT and α-methyl-5-HT were potent, full agonists as measured by PI turnover and [Ca^{2+}]_i mobilization in the uterine cells whilst R-DOI, a prototypic 2A agonist, was less active. Although both 5-HT and α-methyl-5-HT are considered nonselective 5-HT_2 agonists, previous studies comparing cloned human 5-HT_2 receptor subtypes have shown α-methyl-5-HT, and to a lesser extent 5-HT, to have a propensity to selectively activate 5-HT_2B receptors (Porter et al., 1999 and Jerman et al., 2001). R-DOI exhibited less activity than might be expected if the receptor was a 5-HT_2A receptor subtype.

The reportedly 5-HT_2C selective piperazines, mCPP and MK-212, exhibited a weak potency in the agonist assays and mCPP consistently produced partial efficacy. Our findings are in good agreement with previous studies showing mCPP to be a weak,
partial agonist at the 2B receptor (Baxter et al., 1994, Porter et al., 1999, Rothman et al., 2000 and Vickers et al., 2001). Others have observed that mCPP displays no intrinsic agonist activity and acts as an antagonist at the cloned human 5-HT$_{2B}$ receptor (Wood et al., 1997 and Thomas et al., 1996). As a weak, partial agonist at the 2B receptor, mCPP may behave as a functional antagonist in some assay systems.

The tryptamine analog, BW-723C86, has been shown to be a selective agonist for rat (Baxter, 1996; Vickers et al., 2001) and recombinant human (Jerman et al., 2001; Porter et al., 1999) 5-HT$_{2B}$ receptors, although others have found BW-723C86 to be non-selective in receptor binding (Knight et al., 2004) and functional (Cussac et al., 2002) assays. We found that BW-723C86 was a potent agonist for PI hydrolysis assay and calcium mobilization in HUSMCs. This result was in contrast to the very weak 5-HT$_{2}$ agonist activity of BW-723C86 we have observed using the same functional assays in A7r5 rat vascular smooth muscle cells and primary human ocular trabecular meshwork cells (unpublished observations). Similarly, (+)- and (−)-norfenfluramine gave functional profiles consistent with the observed 5HT$_{2B}$-selective potency reported by Porter et al., 1999 at the cloned human 5-HT$_{2B}$ receptor and similar to the activities for the norfenfluramine isomers observed by others in a variety of systems (Fitzgerald et al., 2000, Rothman et al., 2000 and Setola et al., 2003). The high agonist potencies of the BW-723C86 compound and (+)-norfenfluramine exhibited here strongly suggested the presence of a 5-HT$_{2B}$ receptor in the HUSMCs.

A prior study using ketanserin as antagonist suggested 5-HT$_{2A}$ receptors mediate a serotonin-dependent collagenase induction in rat uterine smooth muscle (Rydelek-Fitzgerald et al., 1993) whereas, we find evidence of a 2B receptor in human uterine
smooth muscle. It would be interesting to test currently available subtype selective antagonists for the ability to inhibit 5-HT induction of collagenase in rat uterine cells. It is unclear if rat and human uterine smooth muscle express different 5-HT2 receptor subtypes or possess both 2A and 2B with distinct functions. Rydelek-Fitzgerald and coworkers do note that 5-HT induction of collagenase was unique to the uterine smooth muscle as no such response was observed in rat aortic smooth muscle (Rydelek-Fitzgerald et al., 1993). In human uterine tissue, 5-HT2B receptor mRNA is expressed at high levels and the receptor was cloned from uterine cDNA libraries (Kursar et al., 1994) as well as from the human neuroblastoma cell line, SH-SY5Y (Schmuck et al., 1994). The presence of high levels of 5-HT2B receptor mRNA in human uterine tissue supports our contention that the 5-HT2 receptor signal transduction we observe in HUSMCs can be attributed to the 5-HT2B receptor subtype.

5-HT and α-methyl-5-HT showed stronger potencies for calcium mobilization than PI hydrolysis while BW-723C86 and the other agonists tested were stronger in PI hydrolysis. The reasons for these discrepancies is unclear, though it is tempting to speculate that the increased potency of the nonselective agonists may involve activity at other 5-HT receptors or a greater role of these agonists for the influx of extracellular calcium. Despite these discrepancies, the rank order potencies of agonists derived from our two functional assays are in close agreement (r = 0.9, p<0.005; Figure 5A). Agonist functional data from our studies were also compared to existing data in the literature obtained using rat fundus contraction (Table 1; Baxter et al., 1994) and cloned human 5-HT2B receptor (Table 2, Porter et al., 1999). For a majority of compounds, the potency values were increased in the rat tissue contraction assay versus PI hydrolysis (Table 1).
This is perhaps not surprising considering the inherent differences in assay conditions, including readout, tissue vs. cell culture, and potential species differences. In fact, we observe differences in absolute potency within calcium mobilization between cloned and endogenous human 2B receptors (Table 2) possibly due to differences in receptor density or coupling efficiency. However, our data here are in good agreement with those obtained from cloned human 5-HT_{2B} receptors (r=0.84, p<0.01), and from rat stomach fundus contraction studies (r=0.91, p<0.001; Figure 5B), where endogenous 5HT_{2B} receptors are present.

Subtype-selective antagonists were utilized to more clearly define the 5-HT_{2} receptor subtype responsible for the observed 5-HT response in HUSMCs. In contrast to the lack of selective 5-HT_{2} agonists, potent subtype-specific antagonists are available and routinely used to assign pharmacological actions of potential therapeutics to individual receptor subtypes. M-100907, a potent and selective antagonist for 5-HT_{2A} receptors (Kehne et al., 1996) was ineffective as an inhibitor of 5-HT induced phosphoinositide hydrolysis in HUSMCs (pK_{i}=6.0). This is 1000-fold weaker than binding affinities reported for M-100907 using cloned human 5-HT_{2A} receptor, rat cortex tissues, or other 5-HT_{2A} systems (Kehne et al., 1996).

Similarly, the 5-HT_{2C} selective antagonists, RS-102221 (Bonhaus et al., 1997) and SB-242084 (Kennett et al., 1997) weakly inhibited the 5-HT response, exhibiting potencies substantially less than would be expected from a 5-HT_{2C}-mediated response. Previous studies have identified RS-102221 as a 5-HT_{2C} selective compound with nanomolar affinity for human 5-HT_{2C} receptor (pK_{i}=8.4) as well as nanomolar antagonist potency in a cell-based microphysiometry assay (pA_{2}=8.1) (Bonhaus et al.,
1997). We found RS-102221 to be a very weak inhibitor of 5-HT action in HUSMCs with a pKᵢ = 5.6, approximately 300-fold weaker than observed in 5-HT₂C systems. A second 5-HT₂C specific antagonist, SB-242084, was a more effective inhibitor (pKᵢ = 7.4), yet this potency was 50 – 100-fold weaker than the affinity and potency reported in 5-HT₂C systems and correlated very well with binding affinities reported for this compound at cloned human 5-HT₂B receptors (pKᵢ =7.0) (Kennett et al., 1997).

In contrast, the 5-HT₂B receptor antagonist, RS-127445, was an extremely potent inhibitor of 5-HT-induced PI turnover in HUSMCs (pKᵢ = 9.9) and these results compared favorably with previous studies where RS-127445 displayed subnanomolar affinity at the 5-HT₂B receptor (pKᵢ = 9.5) and potently inhibited both 5-HT-evoked inositol phosphate formation (pKᵢ = 9.5) as well as increases in intracellular calcium (pIC₅₀ = 10.4) in cells expressing human recombinant 5-HT₂B receptors (Bonhaus et al., 1999). RS-127445 has demonstrated 1000-fold selectivity for the 5HT₂B subtype over other 5-HT₂ subtypes (Bonhaus et al., 1999) and has recently been identified as the most selective 2B receptor antagonist currently available (Knight et al., 2004).

Taken together, the pharmacological profile of the serotonergic agonists and subtype-selective antagonists presented here as well as the strong correlation with existing functional data for these compounds in a variety of assay systems provide compelling evidence for the presence of a functional 5-HT₂B receptor in these cultured human uterine smooth muscle cells. The human uterine smooth muscle cells provide a convenient cell-based system for studying the biochemical and pharmacological properties of a human, endogenous 5-HT₂B receptor and allow for profiling the bioactivity of compounds of interest.

collagenase induction in rat myometrial smooth muscle cells: mediation by the 5-HT2

Schroeder KS and Neagle BD (1996) FLIPR: A new instrument for accurate, high
throughput optical screening. J Biomol Screen 1:75-80.

Thomas DR, Gager TL, Holland V, Brown AM and Wood MD (1996) m-Chlorophenylpiperazine (mCPP) is an antagonist at the cloned human 5-HT2B receptor. *NeuroReport* 7:1457-1460.

Legends for Figures

Figure 1. Concentration-dependent phosphoinositide hydrolysis and subsequent $[^3]$H]-inositol phosphates accumulation induced by 5-HT and other serotonergic agonist compounds in human uterine smooth muscle cells. (A) (■) serotonin (5-HT); (●) α-methyl-5-HT; (□) BW-723C86; (○) R-DOI. (B) (▼) (+)-norfenfluramine; (▽) (−)-norfenfluramine; (▲) MK-212; (△) mCPP. Responses induced by the test compounds were represented as a percentage of the maximal response generated by 10µM 5-HT. Data are mean ± S.E.M. from $n \geq 3$ independent experiments.

Figure 2. Concentration-dependent mobilization of [Ca$^{2+}$]_i in response to 5-HT in human uterine smooth muscle cells. Representative fluorescence traces of real-time [Ca$^{2+}$]_i mobilization in HUSMCs loaded with a fluorescent Ca$^{2+}$-sensitive dye and exposed to test compounds for 180 seconds. Trace data is from a single representative experiment that was repeated at least three times. Each data point of the trace is the average fluorescence change from multiple wells.

Figure 3. Concentration-dependent intracellular calcium mobilization induced by 5-HT and other serotonergic agonist compounds in HUSMCs. (A) (■) serotonin (5-HT); (●) α-methyl-5-HT; (□) BW-723C86; (○) R-DOI. (B) (▼) (+)-norfenfluramine; (▽) (−)-norfenfluramine; (▲) MK-212; (△) mCPP. Responses induced by the test compounds
were represented as a percentage of the maximal response generated by 10µM 5-HT.
Data are mean ± S.E.M. from n ≥ 6 independent experiments.

Figure 4. Concentration-dependent inhibition of phosphoinositide hydrolysis by 5-HT2 receptor subtype-selective antagonists. After a 15-min preincubation with varying concentrations of antagonist, cells were exposed to a submaximal concentration of 5-HT agonist (30 nM). (■) RS-127445 (5-HT2B); (▲) SB-242084 (5-HT2C); (●) M-100907 (5-HT2A); (○) RS-102221 (5-HT2C). Values were expressed as a percentage of the response obtained with 30 nM 5-HT alone. Data are mean ± S.E.M. from n ≥ 3 independent experiments.

Figure 5. Correlation of the functional agonist and antagonist potencies of selected serotonergic compounds at the putative 5-HT2B receptors in HUSMC from the present study and functional data from contraction assays in rat stomach fundus. (A) Correlation of agonist potencies determined from the PI turnover assay with agonist potencies determined using the [Ca2+]i mobilization assay. The pEC50 was calculated as -log of the EC50 for each agonist determined in the two assays. (B) Correlation of functional agonist and antagonist potencies using PI turnover assay in the present study (expressed as pEC50; pKi) with rat stomach fundus contraction studies (pEC50; pA2) from Baxter et al., (1994) and MDS PanLabs.
Table 1. Functional agonist activity of serotonergic compounds at the 5-HT$_2$ receptor in human uterine smooth muscle cells (Phosphoinositide hydrolysis). Data are mean ± SEM from n ≥ 3 independent PI turnover experiments. Efficacy values (% E$_{\text{max}}$) are determined relative to 10µM 5-HT as control.

$_{a}$Rat fundus contraction pEC$_{50}$ values were taken from Baxter et al., 1994 and Baxter, 1996.

$_{b}$Rat fundus contraction values were determined at MDS Pharma Services, Taipei, Taiwan.

$_{c}$Schild regression analysis value for inhibition of contraction obtained from Bonhaus et al., 1999.
Table 2. Functional agonist activity of serotonergic compounds at the 5-HT$_2$ receptor in human uterine smooth muscle cells (Intracellular Ca$^{2+}$ Mobilization data). Data are mean ± SEM from n $\geq$ 6 independent [Ca$^{2+}$], mobilization experiments. Efficacy values ($\% E_{\text{max}}$) are determined relative to 10µM 5-HT as control.

$^a$Cloned human 5-HT$_{2B}$ FLIPR pEC$_{50}$ data is from Porter et al., 1999 except where noted.

$^b$Cloned human 5-HT$_{2B}$ pEC$_{50}$ data determined using the Aequorin screening assay at Euroscreen S.A., Brussels, Belgium.
Table 3. Inhibition of 5-HT-induced phosphoinositide hydrolysis by 5-HT$_2$ receptor subtype selective antagonists in human uterine smooth muscle cells. Data are mean $\pm$ SEM from $n \geq 3$ independent PI turnover antagonist experiments. A submaximal 5-HT agonist concentration of 30nM was used for the inhibition studies.
