Abbreviations: ANOVA, analysis of variance; AUC, area under the curve; CORT, corticosterone; CUS, chronic unpredictable stress; DA, dopamine; HPCL-EC, high performance liquid chromatography with electrochemical detection; MDMA, 3,4-methylenedioxymethamphetamine; NO, nitric oxide; PO, preoptic area of the hypothalamus; 5-HT, serotonin

Recommended section assignment: Neuropharmacology
Abstract

Stress facilitates drug abuse by humans. In rodents, stress enhances the neurochemical, neuroendocrine, and behavioral responses to psychostimulants. Although chronic unpredictable stress (CUS) enhances the acute hyperthermic and long-term monoamine depleting effects of the psychostimulant, 3,4-methylenedioxymethamphetamine (MDMA), the roles of hyperthermia and corticosterone (CORT) in mediating the stress-induced enhancement of MDMA-induced serotonin (5-HT) and dopamine (DA) depletions are unknown. Rats were exposed to 10 days of CUS and then challenged with MDMA (5 mg/kg, once every 2 h × 4, i.p.). Prior exposure to CUS augmented MDMA-induced hyperthermia and plasma CORT secretion and the long-term depletions in 5-HT content in striatum, hippocampus, and frontal cortex and DA content in striatum. A reduced ambient temperature of 21°C attenuated the hyperthermia, CORT secretion, and 5-HT decreases after MDMA in non-stressed rats. The lower ambient temperature also prevented the augmented hyperthermia, CORT secretion, and enhanced 5-HT and DA depletions after MDMA in chronically stressed rats to levels exhibited by non-stressed, MDMA-treated rats. To investigate the role of CORT on monoamine depletions in response to MDMA, stressed and non-stressed rats were treated with the CORT synthesis inhibitor, metyrapone, during exposure to MDMA. Metyrapone prevented CORT secretion in both stressed and non-stressed rats but did not modify 5-HT or DA depletions in any brain region examined. This study suggests that enhanced CORT is a consequence of enhanced hyperthermia and that the CUS-induced enhancements of MDMA-induced monoamine depletions may be mediated by hyperthermia but not CORT.
Introduction

Drug abuse by humans is often precipitated by stressful life events (Sinha, 2008). Repeated exposure to stressors also alters the neurobehavioral responses to drugs of abuse in rodent models such that prior exposure to stress facilitates psychostimulant self-administration and reinstates drug-seeking behavior in extinguished animals (Piazza and LeMoal, 1998). The facilitation and reinstatement of drug use can be prevented by adrenalectomy or corticosterone (CORT) synthesis inhibition (Marinelli and Piazza, 2002), suggesting a role for CORT in addiction and relapse. Recently, we demonstrated that prior exposure to chronic unpredictable stress (CUS) enhances +3,4-methylenedioxymethamphetamine (MDMA, Ecstasy)-induced hyperthermia and serotonin (5-HT) depletions and causes a dopamine (DA) depletion in the rat brain, all of which depended on chronic stress-induced elevations in CORT (Johnson and Yamamoto, 2009). These results show that the acute and long-term consequences of MDMA are enhanced by stress in a CORT-dependent manner.

Persistent elevations in CORT result in increased susceptibility not only to substance abuse but also to depression, disease, and cognitive deficits in humans (McEwen 2000; de Kloet et al., 2005; Sinha, 2008). Similarly, chronic stress produces deficits in hippocampal-dependent cognition in rodents (McEwen, 2000) which may be due to CORT-dependent dendritic atrophy in this region (Magarinos and McEwen, 1995). Moreover, chronic stress or exogenous administration of glucocorticoids increases vulnerability to and potentiates hippocampal neuronal damage produced by neurotoxins (Sapolsky, 1985; Stein-Behrens et al., 1994) and enhances monoamine depletions.
induced by MDMA (Johnson and Yamamoto, 2009). The mechanisms of how prolonged stress and neurotoxins interact to enhance neuronal damage have not been fully elucidated but may involve CORT.

MDMA is a widely abused “club drug” and member of the amphetamine family of compounds. High dose MDMA administration to rodents and non-human primates results in long-term, selective decreases in 5-HT nerve terminal markers, such as 5-HT tissue content, activity of tryptophan hydroxylase, and the density of 5-HT reuptake sites in several brain regions including the hippocampus, striatum, and cortex (for review see Baumann et al., 2007). Depletions of 5-HT have been reported to endure for as long as 52 weeks after exposure to MDMA, with the most pronounced and long-lasting decreases occurring in the hippocampus and frontal cortex (Sabol et al., 1996). High dose MDMA produces hippocampal-dependent cognitive deficits in rodents (Baumann et al., 2007) and cognitive deficits are present in abstinent human MDMA abusers along with decreased 5-HT transporter binding in several regions including the hippocampus (McCann et al., 2008).

Hyperthermia is a major contributor to MDMA-induced 5-HT depletions. The prevention of hyperthermia during MDMA administration attenuates 5-HT depletions, while increasing ambient temperature during MDMA administration enhances depletions of 5-HT (Malberg and Seiden, 1998). In addition to hyperthermia, CORT secretion is also increased by MDMA (Nash et al., 1988) but its role in 5-HT depletions has been controversial. Johnson et al., (1989) demonstrated that adrenalectomized rats supplemented with high CORT and treated with MDMA had enhanced depletions of 5-HT in the hippocampus. Fernandez et al., (2002) found that adrenalectomy attenuated
both MDMA-induced hyperthermia and depletions of 5-HT in striatum. In contrast, Aquirre et al., (1997) found that adrenalectomy did not significantly alter MDMA-induced 5-HT depletions. We have shown that prior exposure to chronic stress potentiates MDMA-induced hyperthermia (Johnson and Yamamoto, 2009) and others have found increases in temperature and CORT in response to a novel stressor after chronic stress exposure (Bhatnagar et al., 2006). However, the effects of CUS on CORT responses to repeated MDMA administration as well as the roles of hyperthermia and CORT in the enhanced 5-HT and DA depletions produced by CUS exposure prior to MDMA are unknown.

The current studies investigated the effects of prior exposure to CUS on MDMA-induced hyperthermia, CORT secretion, and long-term changes in 5-HT and DA tissue content. The roles of hyperthermia and CORT were investigated in both non-stressed and chronically stressed rats by determining the effect of treatment with MDMA at a reduced ambient temperature of 21°C compared to a typical ambient temperature of 24°C and by pharmacologically inhibiting the synthesis of CORT during MDMA administration.
Methods

Animals and stress exposure

Male Sprague-Dawley rats (175-250 g) were purchased from Harlan (Indianapolis, IN). Rats were group housed in clear plastic containers (45 × 24 × 20 cm) with food and water available ad libitum, in a temperature (23 ± 1°C) controlled environment on a 12-h light/dark cycle (lights on 07:00 h and off 19:00 h). All procedures were carried out in accordance with the Boston University and the University of Toledo Institutional Animal Care and Use Committees, as well as with the National Institutes of Health Guide for the Care and Use of Laboratory Animals to ensure that animal numbers and suffering were kept to a minimum.

Stressed rats were exposed to stressors that varied by day and time, two per day, for 10 days. The chronic unpredictable stress model varies the type, time, and exposure length of each stressor to avoid adaptation to the stressors (Herman et al., 1995). This model better mimics unexpected stressful life events encountered by humans. The following schedule was used: day 1: 10:00 h 50 min cold room (4°C) and 13:00 h 60 min restraint; day 2: 11:00 h 60 min cage agitation and 18:00 h lights on overnight; day 3: 10:00 h 3 hr lights off and 15:00 h 3 min swim stress (23°C); day 4: 11:00 h 50 min restraint and 17:00 h food and water deprivation overnight; day 5: 12:00 h 15 min cold room isolation (4°C) and 12:30 h isolation housing overnight; day 6: 10:00 h 4 min swim stress (23°C) and 18:00 h lights on overnight; day 7: 9:00 h 2 h lights off and 18:00 h food and water deprivation overnight; day 8: 10:00 h 30 min restraint and 15:00 h 40 min cage agitation; day 9: 11:00 h 3 min swim stress (23°C) and 18:00 h lights on overnight;
day 10: 10:00 h 3 h lights off and 13:00 h 20 min cage agitation. Non-stressed rats were transported daily to the area where stressors were administered but were not exposed to the stressors. After the completion of each stressor, rats were returned to the housing room.

**Drugs and drug administration**

+3,4-methylenedioxymethamphetamine (MDMA) hydrochloride was provided by the National Institute on Drug Abuse (Rockville, MD). The day after the last stressor (day 11), 5 mg/kg MDMA, dissolved in 0.9% NaCl (saline), or saline was injected intraperitoneally (i.p.) once every 2 h for a total of 4 injections (5 mg/kg; q 2 h × 4) at a volume of 1 ml/kg. MDMA or saline injections were administered in a room with an ambient temperature of 24°C unless otherwise specified. This lower repeated dosing regimen of MDMA was selected for its lesser impact on 5-HT tissue content depletions as determined in preliminary experiments.

2-Methyl-1,2-di-3-pyridyl-1-propanone (metyrapone) was purchased from Sigma-Aldrich (St. Louis, MO). Metyrapone inhibits corticosteroid biosynthesis by binding to 11β-hydroxylase, the enzyme that converts 11-deoxycorticosterone to CORT in the adrenal glands (Sonino, 1982). Metyrapone was dissolved in 10% ethanol and was administered i.p. in a volume of 1 ml/kg. Metyrapone (50 mg/kg) or its vehicle 10% ethanol (1 ml/kg) was administered 2 h and 1 h prior to the first injection of MDMA and then 1 h prior to the second, third, and fourth injections of MDMA. This treatment regimen was effective at preventing MDMA-induced CORT secretion in preliminary experiments.
Temperature measurements and manipulation

On day 10 after the last stressor (17:00 h), rats were moved to treatment rooms maintained at either 21°C or 24°C where they we housed overnight. For the metyrapone experiment, all rats were treated in a room maintained at 24°C. The day after the last stressor (day 11), rats received repeated MDMA (5 mg/kg; q 2 h × 4, i.p.) or saline injections beginning at 9:00 h. Body temperature was measured using a rectal probe digital thermometer (Thermalert TH-8 monitor, Physitemp Instruments, Inc., Clinton, NJ). Temperatures were recorded prior to the first injection of MDMA or saline and 1 h after each injection by holding each rat at the base of the tail and inserting a probe (RET-2) 4.6 cm past the rectum into the colon for 6-8 s until rectal temperature was maintained for 3 s. The enhanced MDMA-induced hyperthermia in rats pre-exposed to CUS was effectively reduced to temperatures similar to those of non-stressed, MDMA-treated rats by treatment in a room maintained at 21°C compared to 24°C as determined in preliminary experiments. Rats were either killed 1 hr after the fourth MDMA or saline injection for CORT measurement or were returned to the housing colony the morning after MDMA or saline injections.

In a preliminary experiment to determine the dosing of metyrapone during MDMA that would effectively prevent increases in CORT secretion, it was determined that metyrapone enhanced MDMA-induced body temperature. In order eliminate body temperature effects on 5-HT depletions, both non-stressed and stressed rats administered metyrapone during MDMA were maintained at body temperatures typical of non-stressed and stressed MDMA-treated rats, respectively, by placing cages on ice water for brief
periods of time. This procedure effectively maintained rectal temperatures similar to those of either non-stressed or stressed rats treated with MDMA.

**Measurement of plasma corticosterone**

Half of the rats from each treatment group were killed by rapid decapitation 1 h after the fourth injection of MDMA or saline. Trunk blood was collected into microcentrifuge tubes on ice, centrifuged at 800 × g for 14 min at 4°C, and the plasma was collected and centrifuged further at 800 × g for 7 min at 4°C. Plasma was stored at -80°C until analysis. Plasma CORT was analyzed using a commercially available EIA (Diagnostic Systems Laboratories, Webster, TX). Data are presented as ng/ml.

**High-performance liquid chromatography for tissue 5-HT and DA content**

Rats from the other half of each treatment group were killed by rapid decapitation 5 days after MDMA or saline treatment. The brains were quickly removed and whole striata, hippocampi, and frontal cortices were dissected and frozen on dry ice. The tissue was stored at -80°C for later analysis of 5-HT and DA tissue content. Tissues were sonicated in cold 0.25 M perchloric acid and centrifuged at 14,000 × g for 20 min at 4°C. The supernatant was analyzed with high-performance liquid chromatography with electrochemical detection (HPLC-EC). Separation of biogenic amines from their metabolites was achieved with a 3 μm particle size reverse phase C-18 column (100 × 2.0 mm, Phenomenex, Torrance, CA) and a mobile phase consisting of 32 mM citric acid, 54.3 mM sodium acetate, 0.074 mM EDTA, 0.22 mM octyl sodium sulfate, and 3% methanol (pH 3.1). Compounds were detected with an LC-4B amperometric detector.
(Bioanalytical Systems, West Lafayette, IN) with a 6 mm glassy carbon working electrode maintained at a potential of +0.6 V relative to an Ag/AgCl reference electrode. Data were collected using EZChrom Elite software (Agilent Technologies, Santa Clara, CA). The pellet was dissolved in 1 N NaOH and protein content was determined using a Bradford assay (Bio-Rad, Hercules, CA). Data are presented as pg/μg protein.

**Statistical analyses**

Rectal temperatures were analyzed using a three-way ANOVA with repeated-measures with treatment as the between-subjects factor and time as the repeated-measures factor. Three-way ANOVAs were used for the analysis of area under the curve for rectal temperatures, CORT, and 5-HT and DA tissue content. ANOVAs were followed by Tukey’s post hoc comparisons. Statistical significance was set at p<0.05 for all tests. Figure legends contain the sample sizes.
Results

Impact of CUS on MDMA-induced hyperthermia at ambient temperatures of 21°C and 24°C

Figure 1A illustrates body temperatures in response to MDMA (5 mg/kg; q 2 h × 4, i.p.) or saline administered at ambient temperatures of 21°C or 24°C to stressed and non-stressed rats. A three-way repeated measures ANOVA showed main effects of treatment (F\(_{7,409}\) = 169.76, \(p<0.001\)) and time (F\(_{4,409}\) = 74.39, \(p<0.001\)) and a treatment × time interaction (F\(_{28,409}\) = 16.99, \(p<0.001\)). Figure 1B illustrates body temperatures as an area under the curve (AUC). An AUC was generated for each rat using a trapezoidal AUC analysis. A three way ANOVA revealed main effects of stress (F\(_{1,80}\) = 58.026, \(p<0.001\)), MDMA (F\(_{1,80}\) = 494.5, \(p<0.001\)), and ambient temperature (F\(_{1,80}\) = 128.2, \(p<0.001\)), as well as significant stress × MDMA (F\(_{1,80}\) = 56.163, \(p<0.001\)), MDMA × ambient temperature (F\(_{1,80}\) = 28.786, \(p<0.001\)) and stress × MDMA × ambient temperature (F\(_{1,80}\) = 5.371, \(p<0.05\)) interactions. A two-way ANOVA within the MDMA-treated groups showed a stress × ambient temperature interaction (F\(_{1,42}\) = 4.442, \(p<0.05\)). The post hoc analysis revealed significant enhancements in body temperature between non-stressed and stressed rats treated with MDMA at both 21°C (\(p<0.001\)) and 24°C (\(p<0.001\)) and significant attenuation of increases in body temperatures between non-stressed rats treated with MDMA at 21°C compared to 24°C (\(p<0.001\)) and between stressed rats treated with MDMA at 21°C compared to 24°C (\(p<0.001\)).

Impact of CUS on MDMA-induced plasma CORT at ambient temperatures of 21°C and 24°C
Figure 2 illustrates plasma CORT levels measured 1 h after the last injection of MDMA (5 mg/kg; q 2 h × 4, i.p.) or saline administered at ambient temperatures of 21°C or 24°C to stressed and non-stressed rats. A three-way ANOVA showed main effects of stress (F\(_{1,49} = 5.111, p<0.05\)), MDMA (F\(_{1,49} = 94.941, p<0.001\)), and ambient temperature (F\(_{1,49} = 17.666, p<0.001\)), as well as significant stress × MDMA (F\(_{1,49} = 21.301, p<0.001\)), stress × ambient temperature (F\(_{1,49} = 9.641, p<0.01\)), and MDMA × ambient temperature (F\(_{1,49} = 23.921, p<0.001\)) interactions, however the stress × MDMA × ambient temperature interaction was not significant (F\(_{1,49} = 0.105, p>0.05\)). Post hoc comparisons revealed that MDMA had a greater effect on CORT compared to saline in both non-stressed (p<0.05) and stressed (p<0.001) rats. MDMA had a greater effect on CORT in stressed compared to non-stressed rats (p<0.001). MDMA also had a greater effect on CORT among rats treated at 24°C compared to rats treated with MDMA at 21°C (p<0.01). MDMA administration produced a greater effect on CORT compared to saline administration among rats treated at either 21°C (p<0.001) or 24°C (p<0.01). Within the saline-treated rats there was no effect of stress compared to no stress on CORT (p>0.05) nor was there an effect of ambient temperature (21°C vs. 24°C) on CORT (p>0.05). A two-way ANOVA within MDMA-treated rats revealed a significant stress × ambient temperature interaction (F\(_{1,27} = 4.259, p=0.05\)). Post hoc comparisons indicated that MDMA caused a greater increase in CORT in stressed compared to non-stressed rats at both 21°C (p<0.001) and 24°C (p<0.001) and that CORT levels were reduced by treatment of MDMA at 21°C compared to 24°C in both non-stressed (p<0.01) and stressed (p<0.001) rats.
Impact of CUS on MDMA-induced 5-HT and DA depletions at ambient temperatures of 21°C and 24°C

Figure 3 illustrates 5-HT and DA tissue content in the striatum, hippocampus, and frontal cortex measured 5 days after MDMA (5 mg/kg; q 2 h × 4, i.p.) or saline administration at ambient temperatures of 21°C or 24°C to stressed and non-stressed rats. HPLC-EC peaks for DA in the hippocampus were below the detection limit and therefore not measured.

**Striatum.** A three-way ANOVA of 5-HT tissue content in the striatum (Fig. 3A), revealed main effects of stress (F$_{1,43} = 10.908$, p<0.01), MDMA (F$_{1,43} = 107.577$, p<0.001), and ambient temperature (F$_{1,43} = 14.789$, p<0.001) as well as stress × MDMA (F$_{1,43} = 13.784$, p<0.001) and MDMA × ambient temperature (F$_{1,43} = 5.87$, p<0.05) interactions. There was no stress × MDMA × ambient temperature interaction (F$_{1,43} = 0.032$, p>0.05). Post hoc comparisons confirm that MDMA produced a significant depletion in 5-HT content as compared to saline controls (p<0.001) and prior exposure to CUS enhanced this depletion (p<0.001). A two-way ANOVA within MDMA-treated groups confirmed the ability of CUS to increase 5-HT depletions (F$_{1,21} = 35.495$, p<0.001) and revealed a main effect of ambient temperature (F$_{1,21} = 28.339$, p<0.001). Post hoc comparisons showed that treatment with MDMA at 21°C prevented the enhancements in 5-HT depletions compared to treatment at 24°C (p<0.001). Analysis of DA content in the striatum (Fig. 3B) revealed main effects of stress (F$_{1,43} = 7.735$, p<0.01), MDMA (F$_{1,43} = 14.095$, p<0.001), and ambient temperature (F$_{1,43} = 6.095$, p<0.05) as well as stress × ambient temperature (F$_{1,43} = 5.989$, p<0.05) and MDMA × ambient temperature (F$_{1,43} = 3.798$, p=0.05) interactions, but did not show a stress × MDMA × ambient temperature interaction (F$_{1,43} = 1.492$, p>0.05). Post hoc comparisons
indicated that MDMA had no effect on DA content in non-stressed rats compared to saline controls (p>0.05), but that MDMA produced a significant depletion in DA content in stressed rats (p<0.001). A two-way ANOVA within MDMA-treated groups confirmed the ability of CUS to produce a DA depletion in stressed compared to non-stressed rats (F1,21 = 8.127, p<0.05) and indicated a main effect of ambient temperature (F1,21 = 7.12, p<0.05). Post hoc comparisons revealed that treatment with MDMA at 21°C prevented the enhanced DA depletion compared to treatment at 24°C (p<0.01).

**Hippocampus.** A three-way ANOVA of 5-HT tissue content in the hippocampus (Fig. 3C), revealed main effects of stress (F1,43 = 9.565, p<0.01), MDMA (F1,43 = 142.347, p<0.001), and ambient temperature (F1,43 = 11.155, p<0.01) as well as stress × MDMA (F1,43 = 4.753, p<0.05) and MDMA × ambient temperature (F1,43 = 6.217, p<0.05) interactions, but did not find a stress × MDMA × ambient temperature interaction (F1,43 = 0.285, p>0.05). Post hoc comparisons confirmed that MDMA produced a significant depletion in 5-HT content as compared to saline controls (p<0.001) and prior exposure to CUS enhanced this depletion (p<0.001). A two-way ANOVA within MDMA-treated groups confirmed the ability of CUS to increase 5-HT depletions (F1,21 = 11.6, p<0.01) and showed a main effect of ambient temperature (F1,21 = 14.198, p<0.01). Post hoc comparisons revealed that treatment with MDMA at 21°C prevented the enhancements in 5-HT depletions compared to treatment at 24°C (p<0.01).

**Frontal Cortex.** A three-way ANOVA of 5-HT tissue content in the frontal cortex (Fig. 3D) revealed main effects of stress (F1,43 = 9.385, p<0.01), MDMA (F1,43 = 212.887, p<0.001), and ambient temperature (F1,43 = 9.154, p<0.01) as well as stress × MDMA (F1,43 = 12.262, p<0.01) and MDMA × ambient temperature (F1,43 = 8.626, p<0.01)
interactions. There was no stress × MDMA × ambient temperature interaction (F1,43 = 1.41, p>0.05). Post hoc comparisons confirmed that MDMA produced a significant depletion in 5-HT content as compared to saline controls (p<0.001) and prior exposure to CUS enhanced this depletion (p<0.001). A two-way ANOVA within MDMA-treated groups confirmed the ability of CUS to increase 5-HT depletions (F1,21 = 31.438, p<0.001) and revealed a main effect of ambient temperature (F1,21 = 25.933, p<0.001). Post hoc comparisons showed that treatment with MDMA at 21°C prevented the enhancements in 5-HT depletions compared to treatment at 24°C (p<0.001). There were no main effects of stress (F1,43 = 0.128, p>0.05), MDMA (F1,43 = 0.277, p>0.05), ambient temperature (F1,43 = 0.0238, p>0.05), or a stress × MDMA × ambient temperature interaction (F1,43 = 0.0002, p>0.05) on DA content in the frontal cortex (Fig. 3E).

Effect of Metyrapone Administration during MDMA on Body Temperature

Figure 4 illustrates rectal temperatures in response to MDMA (5 mg/kg; q 2h × 4, i.p.) or saline administration of stressed and non-stressed rats also receiving vehicle (10% EtOH, 1 ml/kg, i.p.) or metyrapone (50 mg/kg, i.p.) 2 h and 1 h prior to the first MDMA or saline injection and 1 h prior to the second, third, and fourth injections. The body temperatures of MDMA-treated, non-stressed and stressed rats that received metyrapone were maintained at body temperatures typical of rats in these treatment groups that received vehicle instead of metyrapone. This was necessary due to a preliminary finding that metyrapone enhanced hyperthermia in MDMA-treated rats. A three-way repeated measures ANOVA showed main effects of treatment (F7,424 = 197.15, p<0.001) and time (F4,424 = 136.69, p<0.001) and a treatment × time interaction (F28,424 = 25.24, p<0.001).
Post hoc comparisons indicated that MDMA administration to non-stressed rats resulted in increases in body temperature compared to saline-treated rats 1 h after the 2nd (p<0.001), 3rd (p<0.001), and 4th (p<0.001) injections and administration of MDMA to stressed rats resulted in increases in body temperature compared to saline-treated rats 1 h after the 1st (p<0.05), 2nd (p<0.001), 3rd (p<0.001), and 4th (p<0.001) injections. Stressed, MDMA-treated rats exhibited significant increases in body temperature compared to non-stressed, MDMA-treated rats 1 h after the 2nd (p<0.001), 3rd (p<0.001), and 4th (p<0.001) injections of MDMA. There were no temperature differences between vehicle and metyrapone treatments in the non-stressed, MDMA-treated (p>0.05 for all time points) or stressed, MDMA-treated (p>0.05 for all time points) groups. There were no differences between any of the saline-treated groups whether they were stressed or non-stressed, or treated with vehicle or metyrapone during saline treatment (p>0.05 for all time points).

**Effect of Metyrapone Administration during MDMA on Plasma CORT**

Figure 5 illustrates plasma CORT in response to MDMA (5 mg/kg; q 2 h × 4, i.p.) or saline administration of stressed and non-stressed rats also receiving vehicle (10% EtOH, 1 ml/kg, i.p.) or metyrapone (50 mg/kg, i.p.) 2 h and 1 h prior to the first MDMA or saline injection and 1 h prior to the second, third, and fourth injections. A three-way ANOVA revealed a significant stress × MDMA × metyrapone interaction (F1,41 = 7.744, p<0.01) indicating an increase in CORT after MDMA that was enhanced by prior exposure to CUS and prevented by metyrapone administration during MDMA. Metyrapone administration during MDMA to both non-stressed and stressed rats prevented increases in CORT. Analysis within MDMA-treated groups revealed a stress ×
metyrapone interaction ($F_{1.21} = 16.622$, $p<0.001$), confirming the stress-induced enhancement in MDMA-induced CORT as well as the prevention of MDMA-induced CORT with metyrapone. A post hoc comparison shows that prior exposure to CUS enhanced CORT compared to non-stressed, MDMA-treated rats ($p<0.001$). Metyrapone administration during MDMA prevented increases in CORT in non-stressed rats ($p<0.01$) and the enhancements in CORT in stressed rats ($p<0.001$).

Effect of Metyrapone Administration during MDMA on 5-HT and DA Depletions

Figure 6 illustrates 5-HT and DA tissue content in the striatum, hippocampus, and frontal cortex 5 days after MDMA (5 mg/kg; q 2 h × 4, i.p.) or saline administration to stressed and non-stressed rats also receiving vehicle (10% EtOH, 1 ml/kg, i.p.) or metyrapone (50 mg/kg, i.p.) 2 h and 1 h prior to the first MDMA or saline injection and 1 h prior to the second, third, and fourth injections.

Striatum. Analysis of 5-HT tissue content in the striatum (Fig. 6A) revealed a significant effect of MDMA on 5-HT depletion that was enhanced by CUS as noted by a main effect of MDMA ($F_{1.42} = 134.238$, $p<0.001$) and a stress × MDMA interaction ($F_{1.42} = 16.295$, $p<0.001$). The post hoc comparisons confirmed that MDMA produced a 5-HT depletion compared to saline controls ($p<0.001$) and that chronically stressed rats treated with MDMA had enhanced 5-HT depletions compared to non-stressed, MDMA treated rats ($p<0.001$). The three-way ANOVA did not find a stress × MDMA × metyrapone interaction ($F_{1.42} = 0.0576$, $p = 0.812$), nor did the post hoc analysis reveal an effect of metyrapone compared to vehicle treatment during MDMA on 5-HT depletions in either non-stressed ($p>0.05$) or stressed ($p>0.05$) rats. Metyrapone had no effect on 5-HT.
concentrations in either non-stressed (p>0.05) or stressed (p>0.05) rats administered saline. A three-way ANOVA of DA tissue content in the striatum (Fig. 6B) did not find a stress × MDMA × metyrapone interaction (F1,42 = 1.211, p = 0.279), however there was a significant stress × MDMA interaction (F1,42 = 16.748, p<0.001). Post hoc comparisons revealed that MDMA had no effect on DA content in non-stressed rats compared to saline controls (p>0.05) but that MDMA caused a DA depletion in chronically stressed rats compared to non-stressed rats similarly treated with MDMA (p<0.001). There was no effect of metyrapone compared to vehicle treatment during MDMA on DA depletions in either non-stressed (p>0.05) or stressed (p>0.05) rats. Metyrapone had no effect on DA concentrations in either non-stressed (p>0.05) or stressed (p>0.05) rats administered saline.

Hippocampus. Analysis of 5-HT tissue content in the hippocampus (Fig. 6C) revealed a significant effect of MDMA on 5-HT depletion that was enhanced by CUS as noted by a main effect of MDMA (F1,42 = 274.526, p<0.001) and a stress × MDMA interaction (F1,42 = 9.984, p<0.01). The post hoc comparisons confirmed that MDMA produced a 5-HT depletion compared to saline controls (p<0.001) and that chronically stressed rats treated with MDMA had enhanced 5-HT depletions compared to non-stressed, MDMA treated rats (p<0.001). The three-way ANOVA did not find a stress × MDMA × metyrapone interaction (F1,42 = 0.0990, p = 0.755), nor did the post hoc analysis reveal an effect of metyrapone compared to vehicle treatment during MDMA on 5-HT depletions in either non-stressed (p>0.05) or stressed (p>0.05) rats. Metyrapone had no effect on 5-HT concentrations in either non-stressed (p>0.05) or stressed (p>0.05) rats administered saline.
Frontal Cortex. Analysis of 5-HT tissue content in the frontal cortex (Fig. 6D) revealed a significant effect of MDMA on 5-HT depletion that was enhanced by CUS as noted by a main effect of MDMA (F1,42 = 133.571, p<0.001) and a stress × MDMA interaction (F1,42 = 5.202, p<0.05). The post hoc comparisons confirmed that MDMA produced a 5-HT depletion compared to saline controls (p<0.001) and that chronically stressed rats treated with MDMA had enhanced 5-HT depletions compared to non-stressed, MDMA treated rats (p<0.001). The three-way ANOVA did not find a stress × MDMA × metyrapone interaction (F1,42 = 1.166, p = 0.288), nor did the post hoc analysis reveal an effect of metyrapone compared to vehicle treatment during MDMA on 5-HT depletions in either non-stressed (p>0.05) or stressed (p>0.05) rats. Metyrapone had no effect on 5-HT concentrations in either non-stressed (p>0.05) or stressed (p>0.05) rats administered saline. There were no stress × MDMA (F1,36 = 0.165, p=0.687) or stress × MDMA × metyrapone interactions (F1,36 = 0.159, p = 0.693) on DA tissue content in the frontal cortex (Fig. 6E).
Discussion

Prior exposure to CUS enhances acute hyperthermia and plasma CORT responses produced by repeated administration of MDMA as well as enhancing long-term 5-HT tissue content depletions in striatum, hippocampus, and frontal cortex and reducing DA tissue content in striatum. Reduction of ambient temperature attenuates MDMA-induced hyperthermia, CORT secretion, and 5-HT depletions in rats with and without prior CUS exposure, as well as prevents MDMA-induced DA depletions in stressed rats. Administration of the CORT synthesis inhibitor, metyrapone, during MDMA to non-stressed and stressed rats prevents CORT secretion, but does not alter 5-HT or DA depletions. These findings indicate that the increase in CORT after MDMA and the potentiated CORT response to MDMA after CUS are mediated by hyperthermia. Furthermore, the augmented monoamine depletions in MDMA-treated rats with prior CUS exposure are mediated by the hyperthermic response to MDMA and not directly related to the ability of CUS to enhance MDMA-induced CORT.

CUS enhanced the hyperthermia (Figs. 1 and 4) and long-term 5-HT depletions in striatum (Figs. 3A and 6A), hippocampus (Figs. 3C and 6C), and frontal cortex (Figs. 3D and 6D) to MDMA administered in an ambient temperature of 24°C. MDMA caused a DA depletion in striatum (Figs. 3B and 6B) but not in cortex (Figs. 3E and 6E) of stressed compared to non-stressed rats treated at 24°C. These findings replicate previous results (Johnson and Yamamoto, 2009). Although a 3-way interaction was not statistically significant between MDMA treatment, CUS history and ambient temperature, when analyzed with a 2-way ANOVA within MDMA-treated groups,
treatment with MDMA at a reduced ambient temperature of 21°C attenuated the acute hyperthermia and long-term 5-HT depletions in non-stressed rats and prevented stress-induced enhancements in hyperthermia and depletions of 5-HT and DA compared to rats treated at an ambient temperature of 24°C (Figs. 1 and 3). Stressed and non-stressed rats treated with saline at 21°C exhibited a decline in body temperatures (Fig. 1), however neither stress nor the ambient temperature condition changed 5-HT or DA content in saline-treated rats (Fig. 3). These findings agree with studies showing an association between MDMA-induced 5-HT depletions and the degree of hyperthermia (Malberg and Seiden, 1998) and support a role for hyperthermia in monoamine depletions produced by MDMA in CUS-exposed rats. These data also indicate that DA terminals in striatum are sensitive to the enhanced hyperthermic response to MDMA after CUS. The lack of effect on DA terminals in cortex (Fig. 3E) may be explained by findings that these terminals are also relatively insensitive to the known striatal DA neurotoxin, methamphetamine (Gehrke et al., 2003).

An interaction between stress and 5-HT$_{2A}$ receptors within the preoptic area of the hypothalamus (PO) may mediate the ability of CUS to enhance MDMA-induced hyperthermia. Microinjection of the 5-HT$_{2A/C}$ agonist, ±1-(2,5-dimethoxy-4-iodophenyl)-2-amino-propane (DOI), into the rat PO produces hyperthermia (Lin et al., 1998). Exposure to 10 days of CUS increases 5-HT$_{2A}$ mRNA in the PO (Raudensky and Yamamoto, 2008) and DOI-induced hyperthermia is enhanced in rats pre-exposed to 10 days of CUS (Matuszewich and Yamamoto, 2003). The CUS-induced enhancement in methamphetamine-induced hyperthermia is prevented by 5-HT$_{2A/C}$ antagonism with ketanserin during methamphetamine exposure (Doyle and Yamamoto, 2010). 5-HT$_{2A/C}$
receptor activation also mediates MDMA-induced hyperthermia (Schmidt et al., 1990). Therefore, increased 5-HT$_{2A}$ receptors in the PO may also produce enhanced hyperthermia to MDMA after CUS.

The mechanisms by which MDMA and hyperthermia enhance 5-HT depletions after CUS are unknown. One possibility is the role of CORT. MDMA increases CORT secretion in rodents (Nash et al., 1988) and humans (Mas et al., 1999), indicating MDMA itself is a stressor. Furthermore both body temperature and CORT increase in response to a novel stressor after chronic stress (Bhatnagar et al., 2006). Based on analysis within the MDMA-treated groups, the current findings are the first to demonstrate that not only is MDMA-induced CORT secondary to the hyperthermic response, but that prior exposure to CUS enhances MDMA-induced CORT secretion in a hyperthermia-dependent manner (Fig. 2). While CORT in stressed rats is elevated the morning after the last stressor (Johnson and Yamamoto, 2009), CORT levels of stressed rats after injections of saline were similar to those of non-stressed, saline-treated rats at 24°C (Figs. 2 and 5). This can be explained by the finding that while chronic stress elevates basal CORT the morning after the last stressor, CORT levels of stressed rats are equivalent to non-stressed rats by evening (Ottenweller et al., 1994). Injections of saline at 21°C appear to increase CORT compared to the same treatment at 24°C (Fig. 2). These data suggest that reduced ambient temperature is stressful to naïve rats, but stressed rats that have been exposed to cold during CUS are tolerant to decreases in ambient temperature. Whereas CORT secretion and monoamine depletions were attenuated by the reduction in ambient temperature, a specific role for CORT in MDMA-induced monoamine depletions that is independent of hyperthermia could not be established.
The role of CORT in MDMA-induced 5-HT depletions has been investigated using adrenalectomized rats, but the effects were variable. Johnson et al. (1989) found that adrenalectomy attenuated MDMA-induced decreases in tryptophan hydroxylase activity and that adrenalectomy combined with CORT supplementation enhanced MDMA-induced 5-HT depletions. In contrast, Aquirre et al. (1997) found that adrenalectomy did not alter MDMA-induced 5-HT depletions. However, body temperatures were not recorded in either study; therefore the impact of adrenalectomy on MDMA-induced hyperthermia could not be determined.

Fernandez et al., (2002) found that MDMA elicited a lesser hyperthermic response in adrenalectomized compared to sham-operated rats and attenuated 5-HT depletions. However, adrenalectomy removes both the adrenal medulla and adrenal cortex resulting in decreased sympathetic responses to MDMA and consequently, hyperthermia. The hyperthermic response to MDMA involves activation of the sympathetic nervous system and the release of norepinephrine causing cutaneous vasoconstriction and increased body temperature (Sprague et al., 2003). Sympathectomy, ganglionic blockade, or norepinephrine \( \alpha_1 \)- and \( \beta_3 \)-receptor antagonism attenuate MDMA-induced hyperthermia and 5-HT depletions (Pedersen and Blessing, 2001; Fernandez et al., 2002; Sprague et al., 2003), suggesting that sympathetic blockade rather than CORT reduction after adrenalectomy participates in MDMA-induced hyperthermia and neurotoxicity. To address this possible confound, a pharmacological approach to prevent CORT secretion during MDMA administration was used. Administration of the 11\( \beta \)-hydroxylase inhibitor, metyrapone, diminishes stress-induced elevations in plasma CORT without affecting basal levels (Piazza et al., 1994). In the current study,
metyrapone administration during MDMA prevented increases in CORT measured 1 h after the final MDMA injection in both non-stressed and stressed rats without affecting basal concentrations (Fig. 5). While metyrapone blocked MDMA-induced CORT, it did not prevent MDMA-induced 5-HT depletions in either non-stressed or stressed rats in any brain region examined (Fig. 6). The MDMA-induced DA depletion in the striatum of stressed rats was also unaffected by metyrapone (Fig. 6B). Therefore, neither CORT secreted during MDMA nor the enhancement of CORT by prior exposure to CUS produces or enhances monoamine depletions. In contrast, CORT may enhance the stimulant and rewarding properties of MDMA similar to amphetamine and cocaine (Marinelli and Piazza, 2002).

The enhancement of MDMA-induced hyperthermia after CUS may produce monoamine depletions via metabolic and oxidative stress. Environmental hyperthermia decreases endogenous antioxidants, increases nitric oxide (NO) and superoxide production, and consequent lipid peroxidation (Sharma et al., 2000; Chang et al., 2007). Stress causes hyperthermia in both humans (Marazziti et al., 1992) and rodents (Olivier et al., 2003), and chronic stress decreases endogenous antioxidants and mitochondrial function, increases NO production, and produces lipid peroxidation in rodents (Madrigal et al., 2006). MDMA decreases endogenous antioxidants and mitochondrial function, increases the production of free radicals and NO, depletes ATP, and causes lipid peroxidation (Quinton and Yamamoto, 2006). The prevention of MDMA-induced oxidative stress with antioxidants or through NO synthase inhibition blocks 5-HT depletions without affecting hyperthermia (Quinton and Yamamoto, 2006); suggesting oxidative stress is a consequence of hyperthermia. Co-administration of MDMA and the
mitochondrial complex II inhibitor, malonate, produces a DA depletion in striatum (Nixdorf et al., 2001) implicating enhanced oxidative stress as a cause of DA depletions in stressed rats. Thus, the augmented hyperthermic response to MDMA in stressed rats may enhance 5-HT depletions and produce a DA depletion via enhanced production of metabolic and oxidative stress. The ability of CUS exposure to enhance metabolic and oxidative stress in response to MDMA warrants further investigation.

The present study demonstrates that the CUS-induced enhancement in the long-term neurotoxic effects of MDMA is influenced by hyperthermia. This study is the first demonstration that the CORT response to repeated injections of MDMA is enhanced by prior CUS exposure and mediated by hyperthermia. Although the precise mechanisms by which MDMA-induced monoamine depletions are enhanced by CUS remain unknown, our studies demonstrate that while hyperthermia may play some role, acute increases in CORT do not directly impact monoamine depletions. Given the coincidence of stress and drug abuse (Sinha, 2008) and findings that stress enhances the long-term neurotoxic effects of psychostimulants (Matuszewich and Yamamoto, 2004; Johnson and Yamamoto, 2009; Doyle and Yamamoto, 2010), the current study emphasizes the importance of understanding how stress and psychostimulants interact to contribute to enhanced drug use and associated long-term deleterious consequences.
