## Pharmacokinetic Data Analysis

The exposure at the target site in the brain can rarely be quantified directly. In the cisterna magna ported (CMP) rhesus monkey model exposure can be measured in cerebrospinal fluid (CSF) in addition to plasma. The pharmacokinetics (PK) in plasma and CSF can be used to derive a measure of exposure at the target site. Therefore, a population PK model was developed that describes the PK of MBi-5 in plasma and CSF in CMP rhesus monkeys. The results of the PK analysis of MBi-5 were included in the subsequent PK-PD analysis.

The PK model was developed and fitted to the data by means of non-linear mixed effects modeling using the NONMEM software package version VI level 2 (see the Materials and Methods section in associated article).

The compartmental PK model of MBi-5 was based on simultaneous analysis of plasma and CSF PK data. The PK profiles of MBi-5 in plasma and CSF were adequately described by a model containing three compartments: a central, peripheral and CSF compartment (Supplemental Figure 1). The CSF compartment is linked to the central compartment, with exchange determined by rate constants $K_{32}$ and $K_{23}$. The model considered elimination from the central and CSF compartment, where the elimination from the central compartment ( $K_{20}$ ) is described by the

Michaelis-Menten equation (Supplemental Equation S1).

$$
\begin{equation*}
K_{20}=\frac{V_{M A X}}{K_{M}+\frac{A_{2}}{V_{2}}} \tag{S1}
\end{equation*}
$$

The rate of change in each compartment can be expresses as:

$$
\begin{align*}
& \frac{d}{d t} A_{1}=-K_{a} \times A_{1}  \tag{S2}\\
& \frac{d}{d t} A_{2}=K_{a} \times A_{1}-K_{24} \times A_{2}+K_{42} \times A_{4}-K_{23} \times A_{2}+K_{32} \times A_{3}-\frac{V_{M A X} \times A_{2}}{K_{M}+\frac{A_{2}}{V_{2}}} \tag{S3}
\end{align*}
$$

$$
\begin{equation*}
\frac{d}{d t} A_{3}=K_{23} \times A_{2}-K_{32} \times A_{3}-K_{30} \times A_{3} \tag{S4}
\end{equation*}
$$

$$
\begin{equation*}
\frac{d}{d t} A_{4}=K_{24} \times A_{2}-K_{42} \times A_{4} \tag{S5}
\end{equation*}
$$

MBi-5 displayed nonlinear PK at different kinetic levels. The extent of the absorption decreased with an increase in dose ( $K_{a}$, from 10.0 to $0.144 \mathrm{~h}^{-1}$ for 10 and $125 \mathrm{mg} / \mathrm{kg}$, respectively). The distribution to the CSF compartment appeared to be saturable, reflected in a decrease in the rate constant from the central to CSF compartment for the $125 \mathrm{mg} / \mathrm{kg}$ dose ( $K_{23}$, from 0.000488 to $0.000116 \mathrm{~h}^{-1}$ ). Elimination was identified from the central and CSF compartment. As the
elimination of MBi-5 from the central compartment followed Michaelis-Menten kinetics (Supplemental Equation (S1)) the clearance in the central compartment changed as function of time and concentration $\left(\mathrm{CL}_{2}=\mathrm{K}_{20}(\mathrm{t}, \mathrm{Cp}) \times \mathrm{V}_{2}\right)$. At the doses included in the current investigation, clearance in the CSF compartment $\left(\mathrm{CL}_{3}=\mathrm{K}_{30} * \mathrm{~V}_{3}\right)$ was approximately $10^{6}$-fold greater than clearance from the central compartment, indicating that the CSF clearance route contributes remarkably.

Table 1 shows all PK parameter estimates. The volume of the CSF compartment could not be estimated and was fixed to a small value ( 0.0250 L ). Interanimial variability was quantified for the volume of the central compartment $\left(V_{2}\right)$. Residual variability (proportional error) was higher for the CSF than for the plasma concentration ( 0.628 and 0.188 for CSF and plasma, respectively).

The developed PK model gives an adequate description of plasma and CSF concentration time profiles, as can be seen from plots of the simulated and observed concentrations versus time profiles with 90\% confidence interval (Supplemental Figure 2).

PK data from the CMP rhesus monkey show that there is substantial CSF exposure after oral dosing ( 10 fold lower than in plasma). The data suggest that MBi-5 concentrations in brain, expected to be in between plasma and CSF levels, are sufficient to adequately inhibit $\beta$-secretase activity in brain. The plasma and CSF concentrations versus time profiles predicted from the model had a good fit to the values observed in the rhesus monkeys. Thus, the model could serve as input for PD model analysis.

Supplemental Table 1: Population parameter estimates including coefficient of variation (CV\%) for the PK model of MBi-5

| PARAMETER | DESCRIPTION | VALUE | UNIT | CV\% |
| :---: | :---: | :---: | :---: | :---: |
| Structural parameters |  |  |  |  |
| $\mathrm{V}_{2}$ | central volume | 122 | L | 18.9 |

Supplemental Figure 1: Schematic of the population PK model for MBi-5, that comprised of a dose, central, peripheral and CSF compartment. Rate constants for the individual compartments are $K_{a}$ (absorption), $K_{24}$ (rate constant from central to peripheral), $K_{42}$ (rate constant from peripheral to central), $K_{23}$ (rate constant from central to CSF), $K_{32}$ (rate constant from CSF to central). A1, A2, A3, A4, $V_{2}, V_{3}$ and $V_{4}$ are amounts (A) and volume of distribution (V) of MBi-5 in dose, central, CSF and peripheral compartments, respectively. $K_{30}$ is the elimination rate in CSF compartment. $V_{\text {max }}$ is the maximum velocity; $K_{m}$ is the Michaelis-Menten constant.

Supplemental Figure 2: Visual predictive check of plasma (left panels) and CSF (right panels) concentration time profile of $\mathrm{MBi}-5$ in the rhesus with $90 \%$ confidence interval. The rhesus were administrated with $10 \mathrm{mg} / \mathrm{kg}$ (A) (B), $30 \mathrm{mg} / \mathrm{kg}$ (C) (D) and $125 \mathrm{mg} / \mathrm{kg}$ (E) (F) MBi-5. Observation sample size: $\mathrm{n}=102$ for plasma and CSF per dose from 6 monkeys collected over 7 days.
Plus-symbols represent observed measurements. Dotted line corresponds to the median observed profile. Solid lines show the median simulated profiles. The longs-dashed lines correspond to the $90 \%$ prediction intervals obtained from 1000 individual simulated profiles.
