ABSTRACT

The nutritional compound capsaicin is the major spicy ingredient of chili peppers. Although traditionally associated with analgesic activity, recent studies have shown that capsaicin has profound antineoplastic effects in several types of human cancers. However, the applications of capsaicin as a clinically viable drug are limited by its unpleasant side effects, such as gastric irritation, stomach cramps, and burning sensation. This has led to extensive research focused on the identification and rational design of second-generation capsaicin analogs, which possess greater bioactivity

than capsaicin. A majority of these natural capsaicinoids and synthetic capsaicin analogs have been studied for their pain-relieving activity. Only a few of these capsaicin analogs have been investigated for their anticancer activity in cell culture and animal models. The present review summarizes the current knowledge of the growth-inhibitory activity of natural capsaicinoids and synthetic capsaicin analogs. Future studies that examine the anticancer activity of a greater number of capsaicin analogs represent novel strategies in the treatment of human cancers.

Introduction: Capsaicin

Capsaicin (trans-8-methyl-N-vanillyl-6-nonenamide; Fig. 1A) is the principal, pungent ingredient of chili peppers in the plant genus *Capsicum*. The compound can be found predominantly within the white pith and membrane of both cayenne and chili peppers (Chapa-Oliver and Mejia-Teniente, 2016). It is a potent analgesic and is used topically to treat pain and inflammation associated with a variety of

diseases (O'Neill et al., 2012; Basith et al., 2016). The analgesic activity of capsaicin is mediated by transient receptor potential subfamily vanilloid member 1 receptor (TRPV1), which belongs to the transient receptor potential superfamily of cation-channel receptors (Chen et al., 2014). The transient receptor potential vanilloid receptor family is comprised of six members (TRPV1–6). Capsaicin functions as a classic agonist of the TRPV1 receptor (Caterina et al., 1997). The binding of TRPV1 to capsaicin triggers a plethora of molecular events ultimately inducing to depletion of substance P, desensitization of sensory neurons leading to its analgesic activity. This paved the way for the isolation, design, and synthesis of capsaicin-like compounds (which were TRPV1 agonists) that displayed more potent analgesic activity than capsaicin.

Emerging evidence shows that capsaicin displays anticancer activity in several human cancers, both in cell culture and mice models (for excellent reviews, please refer to (Díaz-Laviada and Rodriguez-Henche, 2014; Basith et al., 2016; Chapa-Oliver and Mejia-Teniente, 2016; Clark and Lee, 2016; Srinivasan, 2016). This led researchers to conjecture that natural and synthetic TRPV1 agonists would display growth-inhibitory effects analogous

to capsaicin. Because a large number of TRPV1 agonists (which had been tested for analgesic activity) had already been described in literature, they were initially investigated for their anticancer activity. However, a majority of research studies have shown that the anticancer activity of capsaicin and capsaicin analogs is completely independent of TRPV1 receptor. This is true of both natural capsaicinoids and synthetic capsaicin mimetics (the reader is referred to excellent reviews and papers (Basith et al.; Chapa-Oliver and Mejia-Teniente, 2016; Clark and Lee, 2016; Zigioli et al., 2009)). Although these natural and synthetic capsaicin mimetics are TRPV1 ligands, their anticancer activity does not involve the TRPV1 receptor (Lau et al., 2012). The anticancer activity of capsaicinoids is mediated through the direct interaction of these compounds with key signaling molecules of the cytoplasmic, mitochondrial, and metabolic survival pathways (Díaz-Laviada and Rodríguez-Henche, 2014; Basith et al., 2016; Chapa-Oliver and Mejia-Teniente, 2016; Clark and Lee, 2016; Srinivasan, 2016). The cellular pathways underlying the anticancer activity of capsaicin are not fully understood; however, multiple mechanisms such as increase of intracellular calcium, induction of calpain activity, reactive oxygen species (ROS) generation, inhibition of coenzyme Q, suppression of mitochondrial respiration, and inhibition of transcription factors like p53, signal transducer and activator of transcription (STAT)3, and nuclear factor κ B have been shown to be involved (for excellent reviews, see Bode and Dong, 2011; Lau et al., 2012; Clark and Lee, 2016; Fernandes et al., 2016; Cho et al., 2017). In addition to suppressing the growth of human cancer cells, capsaicin

promotes the apoptotic activity of cancer chemotherapy agents by multiple mechanisms (Huh et al., 2011; Arzuman et al., 2016; Clark and Lee, 2016; Friedman et al., 2017; Vendrely et al., 2017). For example, capsaicin has been reported to inhibit p-glycoprotein efflux transporters in KB-C2 human endocervical adenocarcinoma cells. The presence of capsaicin in vinblastine-treated KB-C2 cells increases the concentration of the vinblastine (Khan et al., 2015b) in the cellular microenvironment and thereby sensitizes these cells to undergo apoptosis. The p-glycoprotein is a well-characterized transmembrane ATP-binding cassette, multidrug resistance 1 transporter involved in efflux of numerous drugs and other xenobiotics (Silva et al., 2015).

The development of capsaicin as a clinically useful drug for pain relief or cancer therapy is hindered by its adverse side effects. The topical or oral administration of capsaicin in humans causes skin redness, hyperalgesia, nausea, intense tearing in the eyes, conjunctivitis, blepharospasm (sustained, forced, involuntary closing of the eyelids), vomiting, abdominal pain, stomach cramps, bronchospasm, and burning diarrhea (Drewes et al., 2003; Hammer, 2006; Evangelista, 2015). Clinical trials exploring the pain-relieving activity of capsaicin have shown that such side effects have resulted in patients discontinuing use of capsaicin due to its strong pungency and nociceptive effect (Drewes et al., 2003; Hammer, 2006; Evangelista, 2015). Such observations have led to research focused on the discovery and design of capsaicin-like compounds, which display greater anticancer activity than capsaicin with a gentler side effect profile.

Another incentive for the design of capsaicin-based drug candidates is to obtain compounds endowed with improved pharmacological activity, bioavailability, biologic half-life, selectivity, specificity, and therapeutic index relative to capsaicin (Lau et al., 2012). The anticancer activity of capsaicin is covered in several review articles (Khan et al., 2015a; Chapa-Oliver and Mejia-Teniente, 2016; Clark and Lee, 2016). However, the anticancer activity of these natural and synthetic capsaicin-like compounds has yet to be summarized. The present review fills this void of knowledge and discusses the growth-suppressive activity of natural and synthetic capsaicin-like compounds in human cancers. Specifically, the growth-inhibitory activity of these in both tissue culture and animal models will be discussed. We believe that this detailed discussion of the anticancer activity of capsaicin analogs is both timely and relevant, for the potential applications of such compounds in cancer therapy.

Structure Activity Relationship of Capsaicin

The potential clinical application of capsaicin is restricted by its unfavorable side-effect profile. Clinical studies investigating the analgesic activity of capsaicin have shown that oral capsaicin administration in humans leads to intense abdominal pain, hyperalgesia, stomach cramps, and nausea (O'Neill et al., 2012; Basith et al., 2016). These adverse side effects have caused patients to abandon taking capsaicin. This has led to intense research involving capsaicin structure activity relationship studies to isolate or develop new, less irritating analogs (Drewes et al., 2003; Hammer, 2006; Evangelista, 2015). A second driving force behind the identification and synthesis of capsaicin analogs is that of novel drug discovery that aims to generate new capsaicin mimetics with better pharmacological and therapeutic profile than the parent molecule. The structure of capsaicin can be broken down into three major areas, which are depicted in Fig. 1A. The three major regions are as follows: aromatic (Region A), amide (Region B), and the hydrophobic (Region C). (Huang et al., 2013; Diaz-Laviada and Rodriguez-Henche, 2014; Basith et al., 2016; Chapa-Oliver and Mejia-Teniente, 2016; Clark and Lee, 2016; Srinivasan, 2016).

Antineoplastic Activity of Natural Capsaicin Analogs

Capsiates. Data from several independent research laboratories have led to the discovery of natural capsaicin-like compounds that resemble the structure of capsaicin but contain variations in Regions A (aromatic), B (amide), or C (hydrophobic). There are few published reports about natural capsaicin-like compounds (capsaicinoids) that have alterations in Region A (Ogasawara et al., 2002; Gavaraskar et al., 2015). However, several capsaicinoids having variations in Region B have been reported to suppress the growth of human cancer cells in cell culture. The nonpungent capsaicinoid, capsiate (Fig. 1B3), is isolated from a strain of peppers called CH-19 Sweet. Apart from capsiate, CH-19 Sweet is also the source for two additional capsiate-like compounds, namely dihydrocapsiate and nordihydrocapsiate (Fig. 1, B4 and B5) (Macho et al., 2003; Watanabe et al., 2011). These three compounds differ from capsaicin in Region B; dihydrocapsiate

and nordihydrocapsiate contain an ester bond instead of an amide bond between the vanillyl motif and the fatty acid side chain. Dihydrocapsiate and nordihydrocapsiate also differ in Region C relative to capsaicin. Dihydrocapsiate and nordihydrocapsiate have only saturated bonds in the alkyl chain of Region C instead of a single double bond observed in capsaicin. Macho et al. (2003) studied the antiapoptotic activity of capsiate, dihydrocapsiate, and nordihydrocapsiate in Jurkat human acute T-cell leukemia cells. They observed that all three compounds induced apoptosis in a concentration-dependent manner when incubated with Jurkat cells.

Several convergent studies have indicated that capsaicin may also function as a tumor promotor in skin cancer, breast cancer, and colon cancer (Bode and Dong, 2011). In contrast, all capsaicin-like compounds (natural capsaicinoids or synthetic capsaicin mimetics) have shown only growth-inhibitory activity toward numerous cell lines (Basith et al., 2016). Nordihydrocapsiate further showed potent chemopreventive activity in an in vivo two-stage model of mouse skin carcinogenesis. These findings would suggest that, in this experimental model and with application of a promotor, nordihydrocapsiate may provide protection against skin cancer (Macho et al., 2003). The mechanism of action of these capsates was similar to capsaicin and was mediated by inhibition of transcription factor nuclear factor κ B, elevation of reactive oxygen species, and loss of mitochondrial membrane potential (Fig. 2A) (Macho et al., 2003; Watanabe et al., 2011). Most interestingly, nordihydrocapsiate showed better proapoptotic activity than capsaicin in Jurkat cells, as reflected by the IC_{50} values (nordihydrocapsiate, $IC_{50} = 75 \mu M$; capsaicin, $IC_{50} = 125 \mu M$) (Macho et al., 2003). Both capsiate and dihydrocapsiate displayed antiangiogenic activity in cell culture and mouse models (Fig. 2A). These compounds suppressed vascular endothelial growth factor-induced angiogenesis in human umbilical cord endothelial cells via direct suppression of Src kinase activity and phosphorylation of its downstream substrates, such as $p125^{FAK}$ and vascular endothelial cadherin. Most interestingly, capsiate and nordihydrocapsiate do not affect autophosphorylation of the vascular endothelial growth factor receptor kinase insert domain/fetal liver kinase (Min et al., 2004; Pyun et al., 2008). The antiangiogenic activities of the two compounds were comparable to each other and to capsaicin. Such nonpungent capsaicinoids (capsiate and its related compounds) may be more applicable in cancer therapy than capsaicin.

Evodiamine and Rutaecarpine. Evodiamine (EVO; Fig. 1B6) and rutaecarpine (RUT; Fig. 1B7) are alkaloids isolated from the fruit of the Chinese medical plant *Evodia rutaecarpa*, otherwise known as Evodia fruit (Yu et al., 2013; Wu et al., 2016, 2017). Capsaicin and EVO share pharmacophore elements, but their lipophilic moiety (Region C) is different, encompassing a saturated isononenyl unsaturated group in capsaicin, and two phenyl rings in evodiamine (Pearce et al., 2004; Wang et al., 2009, 2015; De Petrocellis et al., 2014). Wang et al. (2012, 2015) have performed docking and molecular modeling on the pharmacophore of EVO and capsaicin and observed a remarkable similarity between the pharmacophore of the two compounds (Wang et al., 2012, 2015). EVO has been characterized as a potent, selective agonist of the TRPV1 receptor, similar to capsaicin (Ivanova and Spiteller, 2014; Wang et al., 2016). Cell culture studies show that EVO

Fig. 2. Signaling pathways underlying the anticancer activity of natural capsaicinoids. (A) Capsiate and dihydrocapsiate, (B) EVO and RUT.

displays growth-inhibitory activity in human breast cancer, prostate cancer, leukemia, urothelial cell carcinoma, gastric cancer, osteosarcoma, oral cancer, nonsmall lung cancer, colon cancer, glioma, glioblastoma, thyroid cancer, melanoma, and cervical cancer cells (Lee et al., 2006; Kan et al., 2007; Chen et al., 2010; Du et al., 2013; Fang et al., 2014; Gavaraskar et al., 2015; Huang et al., 2015; Khan et al., 2015a; Sachita et al., 2015; Shen et al., 2015; Hu et al., 2016; Shi et al., 2017; Wu et al., 2017; Yang et al., 2017). However, EVO has been shown to be an antagonist of the aryl hydrocarbon receptor as well (Yu et al., 2010). The growth-suppressive activity of EVO is mediated by cell cycle arrest, apoptosis, and autophagy, which involve a symphony of mechanisms (Fig. 2B), including downregulation of survivin, Akt, STAT3, Mcl-1, B-cell lymphoma-2 (Bcl-2) and cdc-p15, and upregulation of caspase-3, phosphatase and tensin homolog, Bcl-2 associated killer, Bax, Fas ligand, microRNA-429, matrix metalloproteinase-9, Jun kinase, cyclin B1, cdc25c, and cdc2-p161 (Lee et al., 2006; Zhu et al., 2011; Fang et al., 2014; Huang et al., 2015; Khan et al., 2015a; Meng et al., 2015; Peng et al., 2015; Zou et al., 2015; Chen et al., 2016; Han et al., 2016; Li et al., 2016; Liu et al., 2016; Wei et al., 2016; Fan et al., 2017; Wu et al., 2017; Yang et al., 2017). EVO-induced autophagy in human glioblastoma cells is mediated by Jun kinase, Bcl-2, and elevation of Bax, intracellular calcium, and induction of ROS/nitric oxide (Liu et al., 2013a,b). The antitumor activity of EVO has been explored in athymic mouse models of human hepatocellular carcinoma, colon cancer, and renal carcinoma (Zhang et al., 2010; Yang et al., 2013; Wu et al., 2016). The anticancer activity of EVO in hepatocellular cancer (Fig. 2B) may be attributed to its ability to suppress β -catenin-mediated angiogenesis (Shi et al., 2016). In contrast, EVO suppressed the growth of human renal carcinoma cells in vivo by inducing phosphorylation of Bcl-2 (Wu et al., 2016). In addition, EVO targeted breast cancer stem-like cells by activating p53 and p21 expression (Han et al., 2016). In gastric cancer stem cells, EVO inhibited proliferation via inhibition of the Wingless/ β -catenin pathway (Wen et al., 2015).

EVO has been shown to induce apoptosis in drug-resistant human cancer cells. EVO displays antiproliferative activity in camptothecin-resistant human leukemia cells (Pan et al., 2012). The mechanism of EVO-induced G₂/M arrest involves the inhibition of topoisomerase 1 and 2 (Lee et al., 2015).

Similarly, EVO induces cell cycle arrest in Taxol-resistant ovarian cancer cells and in Adriamycin-resistant human breast cancer cells (Liao et al., 2005; Zhong et al., 2015). EVO triggers apoptosis in human colon cancer cells resistant to oxaliplatin and cisplatin (Ogasawara et al., 2001; Wen et al., 2015). EVO sensitizes human cancer cells to the apoptotic effects of chemotherapeutic agents. EVO synergizes with doxorubicin and gemcitabine to produce increased apoptosis in breast cancer and pancreatic cancer cells, respectively (Wei et al., 2012; Wang et al., 2014). Likewise, EVO enhances the efficacy of erlotinib in human lung cancer and in human ovarian cancers (Li et al., 2016). Moreover, EVO sensitizes U87MG human glioblastoma cells to the proapoptotic effects of tumor necrosis factor-related apoptosis-inducing ligand. Hu et al. (2016) observed that EVO sensitizes human gastric cancer cells to the growth-suppressive effects of radiotherapy in vitro and in vivo (Hu et al., 2016). In addition to promoting apoptosis in various cancer cells, EVO alters the ATP-binding cassette subfamily G member 2 breast cancer-resistant protein transporter to increase chemosensitivity of colorectal cancer cells. EVO was not a substrate inhibitor of ABCG2, as EVO diminished ABCG2 protein expression in HCT-116/L-OHP cells, which increased cancer chemosensitivity to cisplatin (Sui et al., 2016). Additional studies are needed to explore whether EVO can modify ABCG2 protein expression in other cancer cells.

EVO displays antimigratory, anti-invasive, and antimetastatic activity in human lung cancer, breast cancer, and nasopharyngeal cancer cells in vitro and in mouse models. EVO exerts antimetastatic activity by multiple mechanisms, such as regulation of matrix metalloproteinase-3 activity, p38 kinase activity, extracellular signal-regulated kinase activity, and Janus kinase/STAT pathway, and downregulation of phosphoglucose isomerase (Du et al., 2013; Peng et al., 2015; Zhao et al., 2015).

RUT is the second major alkaloid isolated from *E. rутae-capra*. It is a potent agonist of TRPV1 (Ivanova and Spiteller, 2014). RUT displayed antiproliferative activity in three-dimensional spheroid models of human breast cancer cells (Guo et al., 2016). The antineoplastic activity of EVO and RUT has led to intense research involving design and synthesis of second-generation EVO-like or RUT-like analogs with improved anticancer activity (Fig. 2B). The reader is referred to some excellent reviews on this subject (Hong et al., 2010;

Li-Weber, 2013; Song et al., 2013; Yu et al., 2013). Further studies are needed to investigate whether TRPV1 signaling pathway plays a role in the anticancer activity of EVO and Rut.

Resiniferatoxin. The capsaicin analog resiniferatoxin (RTX; Fig. 1B8) is a tricyclic diterpene isolated from the latex of the cactus plant *Euphorbia resinifera* (Iadarola and Gonnella, 2013). RTX is one of the most potent TRPV1 agonists ever described in literature (Brown, 2016). As can be seen in the figure above, the structure of capsaicin and RTX closely resembles each other, except that Region C is a diterpene moiety of the daphnane class (Carnevale and Rohacs, 2016). Furthermore, pharmacophore clustering and docking studies reveal a close similarity between the two compounds (Hartel et al., 2006; Athanasiou et al., 2007; Carnevale and Rohacs, 2016; Elokely et al., 2016; Lee et al., 2016). Based on previous studies, four sites represent the pharmacophore of RTX, as follows: 1) 4-hydroxy-3-methoxyphenyl, 2) C20 ester, 3) C3-keto, and 4) orthophenyl groups (Huang et al., 2013). The growth-inhibitory activity of RTX has been investigated in multiple human cancer cells. Of these, RTX caused robust apoptosis in human bladder cancer cell lines (T24, 5637) and in athymic mouse models xenografted with T24 bladder cancer cells (Farfariello et al., 2014). However, it did not trigger cell death in normal human urothelial cells. This observation is interesting because RTX selectively targeted human bladder cancer cells, but not the normal urothelial cells.

RTX mimics capsaicin-producing selective apoptosis for human cancer cells while sparing the normal cells (Lau et al., 2014). However, RTX differs by inducing prolonged cell cycle arrest (within G₀ phase) in IEC-18 rat ileal epithelial cells. Such differences can be explained by the fact that the IEC-18 is an immature epithelial cell line derived from rat intestinal crypt, and therefore its growth characteristics cannot be compared with normal primary adult epithelial cells (Frey et al., 2004). Additionally, species-specific differences between rat and human cell lines may explain the varying response of RTX between IEC-18 and normal urothelial cells. In agreement with other studies, the growth-suppressive effects of RTX were found to be independent of TRPV1 receptor and involved a decrease of cyclin D1 at mRNA and protein levels (Frey et al., 2004).

The compound resiniferanol-9, 13, 14 ortho-phenylacetate (ROPA) is a hydrolysis product of RTX (Fig. 1B9). Frey et al. (2004) investigated the growth-inhibitory activity of ROPA on IEC-18 cells (Frey et al., 2004). ROPA was found to induce a transient protein kinase C-dependent cell cycle arrest in G₁ phase. The cell cycle-inhibitory effects of ROPA were accompanied by a decrease in cyclin D1 levels and simultaneous upregulation of p21 expression (Fig. 3A) (Frey et al., 2004). In contrast, RTX did not have any effect on p21 levels in IEC-18 cells. A remarkable observation was that the growth-inhibitory activity of ROPA as well was found to be independent of the TRPV1 receptor family (Frey et al., 2004). The apoptotic activity of RTX was mediated by diverse mechanisms (Fig. 3A) such as mitochondrial depolarization, generation of reactive oxygen species, suppression of mitochondrial respiration, blockage of protein kinase C, inhibition of cyclin D1, and induction of p21^{waf1/Cip1} (Hartel et al., 2006; Athanasiou et al., 2007; Ziglioli et al., 2009; Farfariello et al., 2014; Vercelli et al., 2014).

Dihydrocapsaicin. The capsaicin analog dihydrocapsaicin (DHC) differs from capsaicin in the hydrophobic Region C. It contains a saturated bond between C6 and C7 carbon atoms of Region C (Fig. 1B2). DHC is less pungent than capsaicin based on the Scoville heat units. The anticancer activity of DHC has been observed in several human cancer cell lines, including human breast cancer cells, colon cancer cells, and gliomas (Oh et al., 2008; Oh and Lim, 2009). A majority of these studies have been done in cell culture. An intriguing observation was that DHC showed greater growth-inhibitory activity than capsaicin in these cell lines. The growth-inhibitory effects of DHC (Fig. 3B) were mediated via cell cycle arrest, apoptosis, and autophagy inhibition of cellular metabolism (Oh et al., 2008; Halme et al., 2016). The antitumor activity of DHC was observed in athymic mouse models of human gliomas as well (Xie et al., 2016). However, the drawback with DHC is that it has pungent and irritant properties like capsaicin (Schneider et al., 2014).

Antineoplastic Activity of Synthetic Capsaicin Analogs

N-Acylvanillamides. Among all synthetic analogs of capsaicin, the N-acylvanillamides (N-AVAMs) are of the most extensively researched for their analgesic activity (Melck et al., 1999; Kobata et al., 2010; Huang et al., 2013).

Fig. 3. Signal transduction pathways mediating the antitumor activity of natural capsaicinoids. (A) RTX and ROPA, (B) DHC.

Fig. 4. A panel of UN-AVAMs that have been investigated for their growth-suppressive activity in cell culture or mice models. (A) Dohevanil. The first number in the rectangular brackets indicates the chain length, and the number after the colon indicates the number of double bonds. For example: [C22:6] written next to dohevanil means dohevanil has a chain length of 20 carbon atoms and 6 double bonds in this alkyl side chain. (B) Olvanil [C18:1]. (C) Rinvanil [C18:1]. (D) Phenylacetylirinvanil (PhAR) [C18:1]. (E) Arvanil [C20:4].

There are numerous studies that have investigated their anticancer activities in diverse human cancer cell lines (Sancho et al., 2003; Stock et al., 2012; Sánchez-Sánchez et al., 2015). This class of compounds is modified in the hydrophobic Region C of capsaicin (Fig. 4). Early studies experimented with substituting the acyl side chain with saturated long-chain lipophilic groups. However, these compounds were inactive (Melck et al., 1999). The introduction of long-chain unsaturated fatty acids fully restored the analgesic activity of these compounds. The N-AVAMs are nonpungent and do not have the unfavorable side effects of capsaicin. Structure activity studies experimented with the magnitude of unsaturation in these side chain and the length of the side chain to yield capsaicin analogs with improved analgesic activity and binding profile to TRPV1 (Huang et al., 2013). Recent studies examined the growth-inhibitory activity of these unsaturated N-AVAMs (UN-AVAMs). Tuoya et al. (2006) demonstrated that the UN-AVAM dohevanil (Fig. 4A) induced a greater magnitude apoptosis in MCF-7 human breast cancer cells than capsaicin in vitro (Tuoya et al., 2006). Appendino et al. (2005) synthesized a panel of UN-AVAM compounds with varying affinity for human TRPV1 receptor (Appendino et al., 2002, 2005). Of these compounds, several studies have investigated the growth-inhibitory activity of olvanil (Fig. 4B), rinvanil (Fig. 4C), and phenylacetylirinvanil (PhAR) (Fig. 4D). The 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays showed that olvanil decreased

the viability of C6 rat glioma cells and EFM-19 breast cancer cells (Melck et al., 1999; Huang et al., 2013) (Fig. 5). Apart from being a potent TRPV1 agonist, these compounds displayed weak binding and activation of cannabinoid receptor 1 (CB1) and competitively inhibited the anandamide membrane transporter. Luviano et al. (2014) studied the growth-inhibitory activity of rinvanil and PhAR in J774, P388, and WEHI-3 mouse leukemic cell lines (Fig. 5). PhAR showed improved growth-inhibitory activity relative to rinvanil and capsaicin in all of the cell lines studied (Luviano et al., 2014). Additionally, PhAR displayed some selectivity for leukemic cell lines relative to normal mouse bone marrow cells (Luviano et al., 2014). However, contradictory findings were found later by Sánchez-Sánchez et al. (2015), who analyzed the antiproliferative and cytotoxic activity in a panel of human cervical cancer cell lines, namely HeLa, CaSki, and ViBo. The growth-inhibitory activity of these compounds varied from cell line to cell line and did not correlate with their binding profile to human TRPV1 receptor (Sánchez-Sánchez et al., 2015). The researchers also observed that rinvanil showed selective growth-inhibitory effects on the cervical cancer cells relative to normal lymphocytes, whereas PhAR showed no selectivity between normal and tumor cells (Sánchez-Sánchez et al., 2015). Such variance in results may be attributed to the nature of the cancer, species-specific differences (human cell lines versus mouse cell lines) and the disparity in the methodology used in the two studies. Whereas the studies

Fig. 5. Signaling pathways underlying the antiproliferative and pro-apoptotic activity of synthetic capsaicin analogs.

performed by Luviano et al. (2014) studied the growth-inhibitory effects of PhAR and rinvanil by the Sulforhodamine B assay, Sánchez-Sánchez et al. (2015) used the lactate dehydrogenase assay to evaluate the effect of PhAR and rinvanil on normal lymphocytes (Luviano et al., 2014; Sánchez-Sánchez et al., 2015).

Di Marzo et al. (2002) developed arvanil, an extremely powerful TRPV1 agonist (Fig. 4E). Arvanil is a very potent agonist of the TRPV1 and CB1 receptor (Di Marzo et al., 2002). It also induces robust inhibition of anandamide membrane transporter and fatty acid amide hydroxylase (Melck et al., 1999; De Petrocellis et al., 2000; Di Marzo et al., 2002; Glaser et al., 2003). Experiments in cell culture systems showed that arvanil suppressed the growth of C6 mouse glioma cells (De Lago et al., 2006), Jurkat human T-cell leukemia cells (Sancho et al., 2003), human breast cancer cells (MCF-7, T-47D, and EFM-19 cell lines), and prostate cancer cells (DU145, PPC-1, and TSU cell lines) (Fig. 5) (Melck et al., 1999; Di Marzo et al., 2000; Li and Moore, 2014). A majority of these studies showed that the growth-suppressive activity of arvanil was independent of TRPV1 and CB1 receptor (Melck et al., 1999). Stock et al. (2012) investigated the antineoplastic activity of arvanil in HG-astrocytoma cells organotypically grown in mouse brain slices (Fig. 5). Arvanil suppressed the growth of HG-astrocytoma at a relatively low concentration of 50 nM (Stock et al., 2012). Subsequently, Stock et al. (2012) confirmed the antineoplastic activity of arvanil in HG-astrocytoma tumors implanted in immunocompromised severe combined immunodeficiency mice. They observed that arvanil suppressed the tumor growth rate of HG astrocytomas better than temozolomide (the standard of care for astrocytoma patients). The survival time of mice administered with arvanil was greater than vehicle-treated mice (Stock et al., 2012). This study administered a combination of arvanil and temozolomide, which showed an increase in survival times compared with either agent administered alone or mice administered with vehicle only (Stock et al., 2012). Stock et al. (2012) observed that the anticancer activity of arvanil in human astrocytomas was dependent on the TRPV1 receptor only (Stock et al., 2012). These results are divergent from those found in human breast and prostate cancer cells (Melck et al., 1999). Such

different observations may be due to differences in the cell biology of neuronal and non-neuronal human cancer cells. Small cell lung cancer is a neuroendocrine tumor characterized by rapid doubling time, aggressive clinical course, and a dismal 5-year survival rate. The N-AVAMs arvanil and olvanil suppressed the invasion of human small cell lung cancer cell lines via the 5' AMP-activated protein kinase pathway (Hurley et al., 2017).

RPF, Epoxide-Based Analogs. de-Sá-Júnior et al. (2013) synthesized a capsaicin mimetic called RPF101 (Fig. 6A). The structure of RPF101 differs from capsaicin, primarily in Region B, where the amide group has been replaced by a bioisosteric sulfonamide (de-Sá-Júnior et al., 2013). The alkyl side chain in Region C was replaced with a benzene moiety. The antiproliferative and apoptotic activity of RPF101 in MCF-7 human breast cancer was greater than capsaicin. RPF101 caused cell shrinkage and pyknosis (Fig. 5) in three-dimensional spheroid cultures of MCF-7 cells (de-Sá-Júnior et al., 2013). RPF101 caused a disruption of mitochondrial membrane potential, dysregulation of microtubule formation, and mitotic catastrophe to induce cell cycle arrest and apoptosis in human breast cancer cells (Fig. 5) (de-Sá-Júnior et al., 2013). The research group further modified RPF101 to produce an analog RPF151 (Fig. 6B) with better stability and aqueous solubility properties (Ferreira et al., 2015). In addition, RPF151 displayed lower hyperalgesia relative to capsaicin. MTT assays showed that RPF151 decreased cell viability better than capsaicin in MDA-MB-231 human breast cancer cells. However, RPF151 did not differentiate between MCF-10A normal human breast epithelial cells and breast cancer cells (Ferreira et al., 2015). The mechanism of action of RPF151 was divergent from RPF101. RPF151 induced cell cycle arrest at S-phase with concomitant decrease in cyclin A, D1, and D3 (Fig. 5). RPF151 also induced apoptosis in MDA-MB-231 cells via downregulation of p21, reduction of mitochondrial membrane potential, and activation of the tumor necrosis factor-related apoptosis-inducing ligand pathway (Ferreira et al., 2015). The antineoplastic activity of RPF151 was analyzed by nude mice model of human breast cancer, where it showed higher antitumor activity than capsaicin. Most remarkably, the growth-suppressive activity of RPF151 is independent of the TRPV1 receptor.

Lewinska et al. (2015) synthesized a constrained capsaicin analog that contained an epoxide motif in Region C of the capsaicin (Fig. 6C). The growth-suppressive activity of capsaicin epoxide (CE) compared with capsaicin was studied in a diverse array of cell lines using the MTT assay (Lewinska et al., 2015). Both capsaicin and CE did not reduce the viability of human dermal fibroblasts. However, CE decreased the viability of NIH/3T3 murine embryonic fibroblasts better than capsaicin (Lewinska et al., 2015). The varying results in this study could be due to species and lineage differences between human dermal fibroblasts and the NIH/3T3 cells. Similarly, the growth-inhibitory activity of CE was found to be better than capsaicin in prostate cancer, breast cancer, cervical cancer, and renal cancer cell lines. The human breast cancer cell line MCF-7 was found to be most responsive to CE-induced cell death (Lewinska et al., 2015). CE was shown to trigger robust apoptosis in these cell lines by inducing oxidative stress (Fig. 5).

Fig. 6. Capsaicin analogs containing a sulfonamide and epoxide motif in their structure trigger apoptosis in human cancer cells. (A) RPF101. (B) RPF151. (C) Capsaicin epoxide.

Miscellaneous Capsaicin Analogs. The TRPV1 antagonist capsazepine (Fig. 7A) displayed potent antitumor activity in human prostate cancer and osteosarcoma cells (Teng et al., 2004; Huang et al., 2006; Lee et al., 2017). Gonzales et al. (2014) showed that capsazepine suppressed the growth of human oral squamous cell carcinoma in cell culture and xenograft models in athymic mice. The apoptotic activity of capsaicin was found to be independent of TRPV1 (Huang et al., 2006). The apoptotic activity of capsazepine was induced by endoplasmic reticulum stress, increase of ROS, followed by increase of intracellular calcium in a phospholipase C-independent pathway (Fig. 8). Capsazepine was also found to be an inhibitor of Janus kinase/STAT3 signaling in prostate cancer cells (Huang et al., 2006). Capsazepine also sensitized A549 lung cancer cells to radiation therapy (Nishino et al., 2016). Thomas et al. (2007, 2011, 2012) synthesized the capsaicin analog nonivamide (Fig. 7B), which decreased the viability of the immortalized human lung epithelial cell line BEAS-2B overexpressing TRPV1 (referred in this work as TRPV1-OE cells) (Thomas et al., 2007, 2011, 2012). Nonivamide and its analog N-(3,4-dihydroxybenzyl)nonamide (Fig. 7C) displayed potent growth-suppressive activity in TRPV1-OE cells, and this process was mediated by the ROS oxidative stress pathway (Thomas et al., 2007). Damião et al. (2014) synthesized a variety of capsaicin analogs (Fig. 7, C–E) and tested for their cytotoxicity in B16F10 (mouse melanoma), SK-MEL-28 (human melanoma), NCI-H1299, NCI-H460 (human lung cancer), SK-BR-3, and MDA-MB-231 (human breast cancers) cell lines (Damião et al., 2014). The capsaicin analog N-(benzo[d][1,3]dioxol-5-ylmethyl)-4-methoxybenzamide (Fig. 7D) decreased the viability of human NCI-H1299 cells and mouse melanoma cells, comparable to capsaicin. Benzo[d][1,3]dioxol-5-ylmethyl hexanoate (Fig. 7E) showed greater growth-inhibitory activity in SK-MEL-28 cells than capsaicin (Damião et al., 2014), whereas its growth-suppressive effects are similar to capsaicin in mouse melanoma cells. Furthermore, the authors performed exploratory data analysis and molecular modeling on these both, N-(benzo[d][1,3]dioxol-5-ylmethyl)-4-methoxybenzamide and

benzo[d][1,3]dioxol-5-ylmethyl hexanoate. These *in silico* experiments suggested that aryl amides, esters, and alkyl esters may be promising scaffolds to develop capsaicin mimetics with improved anticancer activity (Damião et al., 2014). The compound MRS1477 (Fig. 7F), a positive allosteric modulator of TRPV1, was found to be very robust in inducing apoptosis in human breast cancer cells *in vitro* and in athymic mouse model (Naziroğlu et al., 2017). The growth-inhibitory effects of MRS1477 were observed at fivefold lower concentration relative to capsaicin. The proapoptotic activity of MRS1477 was mediated by the TRPV1 receptor (Naziroğlu et al., 2017).

Conclusions and Future Directions

The nutritional compound capsaicin has shown potent anticancer activity in multiple human cancers. However, the therapeutic potential of capsaicin has been limited by its unpleasant side effects. This has led to intense research focused on the discovery and design of natural and synthetic capsaicin-like compounds. A variety of natural capsaicinoids has been isolated from peppers and other natural sources. Similarly, synthetic capsaicin analogs have been designed by manipulating the pharmacophore of capsaicin. Another aim of the rational design of capsaicin analogs has been to find compounds that will display better bioactivity and greater therapeutic index. A promising class of synthetic nonpungent capsaicin mimetics are long-chain unsaturated N-AVAMs. An exciting development in the field of capsaicin analogs has been the synthesis of allosteric TRPV1 modulators for cancer therapy. However, a majority of these capsaicin mimetics have been tested for their analgesic activity and not their anticancer activity. The growth-inhibitory activity of some capsaicin analogs has been predominantly analyzed in cell culture and not in animal models. Such data underline the importance of examining the antineoplastic of different types of synthetic capsaicin mimetics in athymic mouse and patient-derived xenograft models. Capsaicin, capsate, and EVO have

been shown to display potent antiangiogenic activity in both cell culture and mouse models. In contrast, there are no reports of the antiangiogenic activity of other natural and synthetic capsaicin analogs. Another promising area of research is the combinatorial anticancer activity of these

capsaicin analogs with conventional chemotherapy or radiation. The development of nonpungent second-generation capsaicin mimetics with anticancer and antiangiogenic activity will pave the way for novel treatment regimens in human cancers.
