ABSTRACT

Indomethacin, a nonsteroidal anti-inflammatory drug, has been shown to induce white adipocyte differentiation; however, its roles in brown adipocyte differentiation and activation in brown adipose tissue (BAT) and obesity are unknown. To address this issue, we treated mouse brown preadipocytes with different doses of indomethacin, and delivered indomethacin to interscapular BAT (iBAT) of obese mice using implanted osmotic pumps. Indomethacin dose dependently increased brown preadipocyte differentiation and upregulated both mRNA and protein expression of uncoupling protein 1 (UCP1) and peroxisome proliferator-activated receptor (PPAR) γ coactivator 1- α . The mechanistic study showed that indomethacin significantly activated the

reporter driven by the PPAR response element, indicating that indomethacin may work as a PPAR γ agonist in this cell line. Consistently, indomethacin significantly decreased iBAT mass and fasting blood glucose levels in high-fat diet-induced obesity (DIO) mice. Histologic analysis showed that brown adipocytes of indomethacin-treated mice contained smaller lipid droplets compared with control mice, suggesting that indomethacin alleviated the whitening of BAT induced by the high-fat diet. Moreover, indomethacin significantly increased UCP1 mRNA expression in iBAT. Taken together, this study indicates that indomethacin can promote mouse brown adipocyte differentiation, and might increase brown fat and glucose oxidation capacity in DIO mice.

Introduction

In recent decades, obesity has become a major public health problem in developed, and even in developing countries (Ng et al., 2014). More than two-thirds of US adults are considered either overweight or obese (Flegal et al., 2012). Obesity is positively associated with a number of complications including type-2 diabetes, cardiovascular disease, gallbladder disease, osteoarthritis, and even some types of cancers (Jensen et al., 2014). Imbalance between energy intake and expenditure is thought to contribute to obesity (Spiegelman and Flier, 2001). Adipose tissue can be classified into white adipose tissue (WAT) and brown adipose tissue (BAT). WAT is the major site for energy storage, and BAT is the major site for thermogenic

energy expenditure by metabolizing glucose and fatty acids to produce heat. Historically, it was believed that BAT only exists in human neonates. Newly developed technologies, especially positron emission tomography in combination with computed tomography, have demonstrated that adult humans do have BAT (Cypess et al., 2009; van Marken Lichtenbelt et al., 2009; Virtanen et al., 2009).

Despite extensive research, few drugs have been approved for treating obesity by the US Food and Drug Administration (Narayanaswami and Dvoskin, 2017). Currently approved drugs target energy intake either by suppression of appetite (phentermine) or by interfering with nutrient absorption (orlistat). However, these drugs have severe cardiovascular and/or psychiatric side effects, and obesity relapse may occur when stopping the drugs (Kakkar and Dahiya, 2015). Emerging evidence on the role of functional BAT in increasing energy expenditure in human adults opens a new direction for anti-obesity therapy.

Indomethacin was discovered in 1963 (Hart and Boardman, 1963) and approved as a nonsteroidal anti-inflammatory drug by the US Food and Drug Administration in 1965. Indomethacin's anti-inflammatory effect is mainly mediated by inhibiting cyclooxygenases (COX), the key enzymes catalyzing the production of prostaglandins from arachidonic acid (Nalamachu and Wortmann, 2014). The adipogenic effect of indomethacin

ABBREVIATIONS: BAT, brown adipose tissue; COX, cyclooxygenase; COXII, cytochrome c oxidase subunit 2; DIO, diet-induced obesity; eWAT, epididymal white adipose tissue; iBAT interscapular brown adipose tissue; iWAT, inguinal white adipose tissue; PCR, polymerase chain reaction; PPAR, peroxisome proliferator-activated receptor; PPRe, peroxisome proliferator-activated receptor response element; rWAT, retroperitoneal white adipose tissue; WAT, white adipose tissue.

was first documented by Williams and Polakis (1977), who found that addition of insulin and indomethacin significantly induced ATP-citrate lyase activity and biosynthesis of triglycerides during 3T3-L1 adipocyte differentiation. Some researchers speculated that the adipogenic effects of indomethacin could be partly explained by the inhibited production of prostaglandins (Chen and London, 1981). Later, one study demonstrated that ob 17 cells treated with a combination of insulin and indomethacin differentiated into adipocytes more rapidly than the cells treated with insulin alone (Verrando et al., 1981). Other investigators (Négrel et al., 1989; Ye and Serrero, 1998) further confirmed the effect of indomethacin in promoting adipogenic differentiation. The mechanism for this effect of indomethacin was not revealed until Lehmann et al. (1997) reported that indomethacin induced C3H10T1/2 adipocyte differentiation by binding and activating peroxisome proliferator-activated receptor (PPAR) γ . It is well recognized that the differentiation of both white and brown adipocytes from adipose stem cells is regulated by transcriptional factors that include CCAAT/enhancer-binding proteins and PPAR γ (Tontonoz et al., 1994; Wu et al., 1999). PPAR γ is a critical and irreplaceable transcriptional factor in regulation of uncoupling protein 1 (UCP1) expression and brown adipocyte differentiation (Koppen and Kalkhoven, 2010). PPAR γ agonists, such as rosiglitazone, are capable of inducing brown preadipocyte differentiation into mature brown adipocytes (Hwang et al., 2011). However, the effects and underlying mechanisms of indomethacin on brown adipocyte differentiation have not been investigated.

Although a number of studies have investigated adipogenic effects of indomethacin *in vitro*, only a few studies reported the effects of indomethacin on obesity *in vivo*. One study showed that indomethacin supplemented in food (16 mg/kg diet) prevented high-fat diet-induced obesity (DIO) in C57BL/6 mice, but failed to prevent hyperglycemia and impaired glucose tolerance (Fjære et al., 2014). Interestingly, the same group in an earlier study reported that *in vitro* treatment with indomethacin (1 μ M) significantly inhibited UCP1 expression in primary inguinal adipocytes and dietary indomethacin supplementation (16 mg/kg diet) increased weight gain and prevented high-fat diet-induced UCP1 expression in inguinal WAT (iWAT) in male Sv129 mice (Madsen et al., 2010). While the discrepancy between the two *in vivo* studies might be related to different strains of mice used, it is also possible that indomethacin could enhance differentiation of both white and brown adipocytes *in vivo*. To further clarify this issue, we first investigated the effect of indomethacin on brown preadipocyte differentiation and its underlying mechanism *in vitro*. We further conducted a pilot animal study to deliver indomethacin to interscapular BAT (iBAT) of DIO mice to maximize brown differentiation while minimizing white differentiation, leading to desirable outcomes in treating obesity and its associated metabolic disorders.

Materials and Methods

Chemicals and Reagents. For the cell culture work, indomethacin, insulin, triiodothyronine, rosiglitazone, and dimethylsulfoxide were purchased from Sigma (St. Louis, MO). Primary antibody for UCP1 was purchased from Sigma Aldrich and primary antibody for PGC-1 α was purchased from Millipore (Temecula, CA). ERK1/2 and horseradish peroxidase-conjugated goat anti-rabbit antibodies were purchased from Cell Signaling Technology (Danvers, MA). For the animal study, Kolliphor HS15 was a gift from BASF

(Florham Park, NJ), and indomethacin was purchased from Cayman Chemical Company (Ann Arbor, MI).

Cell Culture and Treatment. The murine brown fat cell line was a gift from Dr. Johannes Klein (University of Lubeck, Lubeck, Germany), who generated the cell line from iBAT of newborn C57BL/6 mice. Brown preadipocytes were maintained in Dulbecco's modified Eagle's medium supplemented with 20% fetal bovine serum (Atlanta Biologicals, Flowery Branch, GA) at 37°C humidified atmosphere of 5% CO₂ in air, until they reached confluence (designated as day 0). The cells were differentiated by incubation in the differentiation media containing Dulbecco's modified Eagle's medium supplemented with 20% fetal bovine serum, 1 nM triiodothyronine, and 20 nM insulin, and media were changed every other day until day 5. To study the effects of indomethacin on brown preadipocytes, indomethacin (2, 5, 10, 20, and 50 μ M) or the vehicle control (dimethylsulfoxide) was added at day 0 and replaced with each change of the media during the differentiation process.

Western Blot Analysis. Total cell lysates were prepared using 1X lysis buffer (Cell Signaling Technology), and protein concentrations were determined by the BCA Assay Kit (Thermo Scientific, Waltham, MA). Total cell lysates were subjected to 10% SDS-PAGE and transferred to polyvinylidene difluoride membrane (Bio-Rad, Hercules, CA). The membrane was blocked in 20 mM Tris-HCl, 137 mM NaCl, and 0.1% Tween 20 (pH 7.4) containing 5% nonfat milk. The membrane was immunoblotted with primary antibodies at 4°C overnight followed by secondary antibody conjugated with horseradish peroxidase for 1 hour. The membrane was exposed on X-ray film after being developed by enhanced chemiluminescent western blot detection reagents (Pierce, Rockford, IL). The signal was quantified by densitometry using a ChemiDocXRS+ imaging system with ImageLab software (Bio-Rad).

Quantitative Real-Time Polymerase Chain Reaction (PCR) Analysis. Total RNA was prepared using TRI Reagent (Molecular Research Center, Cincinnati, OH) according to the manufacturer's instructions. Total RNA abundance was quantified using a NanoDrop

ND-1000 spectrophotometer (NanoDrop Technologies, Wilmington, DE). Reverse transcription was carried out using the High Capacity cDNA Reverse Transcription Kit (Thermo Scientific, Pittsburgh, PA) according to the manufacturer's instructions. The mRNA expression of target genes and the housekeeping gene 36B4 was measured quantitatively using PowerUp SYBR Master Mix (Applied Biosystems, Austin, TX). PCR reactions were run in a 96-well format using an ABI 7300HT instrument. Cycle conditions were 50°C for 2 minutes and 95°C for 10 minutes, and then 40 cycles of 95°C for 15 seconds and 60°C for 1 minute. Relative gene expression was calculated using the $2^{-\Delta\Delta C_t}$ method, which normalizes against 36B4. All primer sequences are listed in Table 1.

Total DNA was prepared using TRI Reagent (Molecular Research Center) according to the manufacturer's instructions, and DNA concentrations were quantified using the NanoDrop ND-1000 spectrophotometer (NanoDrop Technologies). Mitochondrial cytochrome C oxidase subunit 2 (COXII) and 18S rRNA control genes were measured quantitatively using PowerUp SYBR Master Mix (Applied Biosystems). PCR reactions were run in a 96-well format using the ABI 7300HT instrument (Applied Biosystems, Foster city, CA). Cycle conditions were 50°C for 2 minutes and 95°C for 10 minutes, and then 40 cycles of 95°C for 15 seconds and 60°C for 1 minute. Relative gene expression was calculated using the $2^{-\Delta\Delta C_t}$ method, which normalizes against 18S rRNA.

Reporter Gene Assays. Brown preadipocytes seeded on 48-well plates were transiently transfected with PPAR response element (PPRE)-luciferase reporter (Addgene plasmid #1015) and β -galactosidase expression plasmid with Lipofectamine 2000 Transfection Reagent and Plus Reagent (Thermo Fisher Scientific, Carlsbad, CA). After 24 hours of transfection, the cells were treated with indomethacin or the vehicle control for 18 hours. The cell lysate was prepared and reporter luciferase and β -galactosidase activities were measured using a GloMax Luminometer (Promega, Madison, WI). Relative luciferase activities were normalized by β -galactosidase activities.

Animal Study. Six-week-old male C57BL/6J mice (The Jackson Laboratory, Bar Harbor, ME) were housed in an animal facility with a 12-hour light/dark cycle. After 1 week of acclimation, mice were fed a high-fat diet (45% kcal from fat, D12451) (Research Diets, New Brunswick, NJ) for 9 weeks, and then the mice were weighed and randomly assigned to either the control or the indomethacin group (three mice/group). Indomethacin (10 mg/ml) dissolved in saline containing 18.75% Kolliphor HS15 (percentage of weight) was put into three ALZET mini-osmotic pumps (model 2006) (DURECT Corporation, Cupertino, CA), which were reported to have a delivery

rate of 0.15 μ l/h. In addition, three pumps delivered only saline and the same concentration of Kolliphor HS15. We connected a piece of silicon tubing at the end of each pump, and sutured the tubing on the mouse back muscle to ensure that the opening of the tubing was on the iBAT of the mouse during pump implantation. Mice had free access to water and food, and their body weight and food intake were recorded weekly. After 4 weeks, mice were euthanized by CO₂ asphyxiation. Blood samples were collected in EDTA-coated tubes. Plasma was obtained by blood centrifugation at 2000g at 4°C for 20 minutes. Organs and tissues were immediately dissected, weighed, and flash-frozen in liquid nitrogen. A portion of WAT and iBAT was fixed with 10% phosphate-buffered saline formalin for histologic analysis. The animal protocol was approved by the Institutional Animal Care and Use Committee of Texas Tech University (protocol number: 16028).

Plasma Lipid Profile. Plasma concentrations of triglycerides, total cholesterol, high-density lipoprotein cholesterol, and very low-density lipoprotein cholesterol were measured using the AU400 clinical chemistry analyzer with enzymatic reagents (Beckman Coulter, Inc., Brea, CA) by following the AU400 procedural manual. Low-density lipoprotein cholesterol concentrations were calculated using the Friedewald formula. Plasma concentrations of nonesterified fatty acids were measured using a nonesterified fatty acids quantification kit (ab65341) from Abcam (Cambridge, MA).

H&E Staining. Tissues were fixed with 10% phosphate-buffered saline formalin for 48 hours. H&E staining was performed by the Department of Pathology at the Texas Tech University Health Sciences Center. Briefly, the paraffin sections of adipose tissues (5 μ m) were dewaxed with xylene and rehydrated with alcohol. The samples were washed with water to remove any reagent residue, incubated with Gill's Hematoxylin II for 4 minutes, and then washed several times using water. The samples were counterstained with eosin for 1 minute. Then the samples were dehydrated through absolute alcohol three times. Finally, samples were cleaned with xylene and mounted with xylene-based mounting medium.

Body Composition. Body composition was measured at weeks 0, 2, and 4 using an EchoMRI Body Composition Analyzer (EchoMRI LLC, Houston, TX) according to the manufacturer's instructions at the Texas Tech University animal facility.

Insulin Tolerance Test. After fasting mice for 4 hours on week 4, blood glucose concentrations were measured by tail snip using the OneTouch Ultra2 Glucometer (LifeScan Europe, Zug, Switzerland) and blood glucose test strips. Insulin (0.75 U/kg body weight) was given to mice via intraperitoneal injection, and blood glucose

TABLE 2

Metabolic parameters of mice in both control and indomethacin-treated groups

Metabolic Parameter	Control	Indomethacin	P value
Body weight (g)	30.73 $\pm$ 1.57	31.30 $\pm$ 2.04	0.41
Body composition			
Fat mass (%)	19.62 $\pm$ 3.05	13.32 $\pm$ 3.07	0.23
Lean mass (%)	79.51 $\pm$ 3.19	83.47 $\pm$ 2.88	0.20

concentrations were measured using the aforementioned method at 15, 30, 45, 60, and 120 minutes post injection.

Statistical Analysis. All data presented in the text, Tables 1 and 2, and Figs. 1–5 are mean $\pm$ S.E.M. Measurements were performed in at least three independent experiments. Statistical analysis was performed using Prism 5 (GraphPad Software, Inc., San Diego, CA). One-way analysis of variance with repeated measures followed by multiple comparisons test (Student-Newman-Keuls method) was performed to determine the differences of group means between the treatment groups in the cell culture study. Student's t test was

performed to compare two group means in the animal study. The level of significance was set at $P < 0.05$.

Results

Indomethacin Stimulated Differentiation of Mouse Brown Preadipocytes. We examined brown preadipocyte differentiation in the presence of increasing doses of indomethacin. Indomethacin dose dependently increased

brown preadipocyte differentiation, as revealed by Oil Red O stained cell morphology (Fig. 1A). Quantitation of lipid accumulation by Oil Red O absorbance indicated that compared with the dimethylsulfoxide control, 20 and 50 μ M of indomethacin significantly increased cellular lipid accumulation by 28% and 50%, respectively (Fig. 1B).

Real-time PCR was performed to measure mRNA expression of brown adipocyte related genes in response to indomethacin in brown adipocytes. Brown adipocyte selective markers, both mRNA (Fig. 1, C and D) and protein levels (Fig. 1E) of UCP1 and PPAR γ coactivator 1- α (PGC-1 α), were upregulated in a dose-dependent manner by indomethacin at 5, 10, and 20 μ M ($P < 0.001$). Adipocyte differentiation markers, PPAR γ and PR domain containing 16 (Prdm16) were also induced by indomethacin in a dose-dependent manner at 5–20 μ M (Fig. 2, A and B), whereas nuclear respiratory factor 1 (Nrf-1) expression was significantly increased by indomethacin only at the high concentration (50 μ M; $P < 0.001$) (Fig. 2C). Furthermore, the DNA content of the cytochrome c oxidase subunit 2 (COXII) gene, one of the mitochondrial biogenesis markers, was significantly increased when cells were treated with 20 or 50 μ M of indomethacin (Fig. 2D).

Induction of PPRE-Driven Luciferase Activity by Indomethacin. The PPRE-driven luciferase activities were

evaluated in mouse brown preadipocytes after transient transfection of PPRE-luciferase cells were treated with indomethacin at the concentrations indicated. The data showed that indomethacin dose dependently activated PPRE-luciferase reporter, reaching significance at 20 μ M in mouse brown preadipocytes (Fig. 2E), indicating that indomethacin may work as a PPAR γ agonist in this cell line.

Metabolic Effects of Local Delivery of Indomethacin to iBAT in Obese Mice. We next investigated the metabolic effects of local delivery of indomethacin to iBAT using ALZET mini-osmotic pumps in DIO mice in vivo. The indomethacin treatment did not change food intake and body weight. However, compared with the control mice, indomethacin-treated mice had a 34% reduction in the percentage of epididymal WAT (eWAT) mass ($P = 0.14$), resulting in a 32% reduction in the percentage of body fat mass ($P = 0.23$) (Table 2). Additionally, indomethacin significantly decreased the percentage of iBAT mass by 13% compared with the control ($P = 0.03$). Fasting blood glucose concentrations were 19% lower in indomethacin-treated mice (185 ± 13.58 mg/dl) compared with the control mice (229 ± 6.84 mg/dl) ($P = 0.02$), although insulin tolerance tests showed no differences between the two groups (data not shown). Fasting blood concentrations of very low-density lipoprotein cholesterol,

Fig. 4. Indomethacin slightly increased browning markers in eWAT. (A) Representative H&E staining images of eWAT. (B) Real-time PCR analysis of the expression of BAT markers, genes involved in fatty acid oxidation, and lipid utilization in eWAT. Data = mean $\pm$ S.E.M. ($n = 3$). * $P < 0.05$ compared with the control group.

high-density lipoprotein cholesterol, and nonesterified fatty acids were similar between the control and indomethacin groups. The indomethacin group had numerically lower fasting blood concentrations of triglyceride, total cholesterol, and low-density lipoprotein cholesterol compared with the control group, but the differences did not reach statistical significance, possibly due to the small sample size together with large variability in response.

Indomethacin Alleviated Brown Fat Whitening and Increased Expression of Genes Involved in Brown Fat Activation in Obese Mice. Since indomethacin was directly delivered to iBAT through ALZET osmotic minipumps, we specifically examined the effects of indomethacin on brown adipocyte morphology and expression of iBAT marker genes. H&E staining of iBAT cells in the control mice had enlarged lipid droplets and enhanced lipid deposition, giving the appearance of whitening of iBAT (Fig. 3A). In contrast, the whitening phenotype was not observed in iBAT cells in indomethacin-treated mice. Compared with the control, indomethacin significantly increased mRNA expression of UCP1, perilipin 1 (Plin1), and perilipin 2 (Plin2) (Fig. 3B). There were no significant differences in other brown markers including Prdm16, PGC-1 α , PPAR γ , mitochondrial

transcription factor A (Tfam), and Nrf-1, in fatty acid β -oxidation genes including acyl-coenzyme A dehydrogenase (Acadm) and cytochrome c oxidase subunit IV isoform 2 (Cox4b), and in lipolysis genes including adipocyte triglyceride lipase (ATGL) and hormone-sensitive lipase (HSL) between the indomethacin-treated and control mice (Fig. 3B).

To evaluate browning of WAT, H&E staining and real-time PCR were performed in both eWAT and iWAT (Figs. 4 and 5). The H&E staining revealed similar morphology in both eWAT and iWAT in the indomethacin-treated mice (Figs. 4A and 5A) compared with the control mice. The expression of UCP1, PGC-1 α , PPAR γ , and Prdm16 was 80% higher in the eWAT isolated from the indomethacin-treated mice compared with the control mice, but this difference did not reach statistical significance (Fig. 4B). However, we observed that lipid utilization genes, Plin1 and Plin2, were significantly higher in eWAT isolated from the indomethacin-treated mice compared with the control mice ($P < 0.05$) (Fig. 4B). Unexpectedly, expression of browning related markers in iWAT tended to be lower in the indomethacin-treated mice compared with the control mice (Fig. 5B). We also measured the expression of genes related to fatty acid oxidation, and lipid utilization in

Fig. 5. Indomethacin slightly inhibited browning markers in iWAT. (A) Representative H&E staining images of iWAT. (B) Gene expression analysis of BAT markers, fatty acid oxidation, and lipid utilization in iWAT. Data = mean $\pm$ S.E.M. ($n = 3$). * $P < 0.05$ compared with the control group.

iWAT, but found no significant difference between the treatment and control groups (Fig. 5B).

Discussion

The effects of indomethacin on brown adipocyte differentiation and activities have not been investigated. Our current study demonstrated that indomethacin stimulated mouse brown adipocyte differentiation by enhancing lipid accumulation and gene expression of brown adipocyte specific markers. We further showed that indomethacin activated the PPAR responsive reporter in mouse brown preadipocytes in vitro. In our pilot animal study, we validated that local delivery of indomethacin to iBAT increased expression of genes involved in thermogenesis in iBAT and improved hyperglycemia found in DIO mice.

Indomethacin stimulated mouse brown adipocyte differentiation via activating PPAR γ , which is consistent with a previous study showing that indomethacin can bind to and activate PPAR γ (Lehmann et al., 1997). In addition, the increased ratio of COXII to 18S rRNA DNA content (COXII/18S) in these cells suggests that mitochondrial biogenesis was enhanced by indomethacin. It has been proposed that

browning effects of PPAR γ agonist may be due to its ability to induce expression of PGC-1 α (Wilson-Fritch et al., 2003; Hondares et al., 2006). In agreement with this, our in vitro study demonstrated that indomethacin increased both mRNA and protein expression of PGC-1 α , a master regulator of mitochondrial biogenesis (Jornayvaz and Shulman, 2010).

To extend our in vitro findings into mice in vivo, we further performed a pilot study to deliver indomethacin directly to the iBAT of DIO mice. We found that indomethacin significantly decreased iBAT mass and induced UCP1 mRNA expression in iBAT. The expression of genes regulating lipid utilization, such as Plin 1 and 2, in iBAT was also increased by indomethacin. These data indicated that iBAT fat burning activity might be increased after local delivery of indomethacin. The results of the animal study demonstrated that delivery of indomethacin to the iBAT alleviated its whitening induced by the high-fat diet. One possible explanation is that indomethacin alleviated iBAT whitening via enhancing UCP1-mediated thermogenesis and fat utilization since our data showed that both UCP1 and lipid droplet proteins, such as Plin 1 and Plin 2, were significantly increased in the iBAT of indomethacin-treated mice. It is believed that lipid droplet proteins, including the Plin family and several others, play

an important role in fat utilization in brown adipocytes (Townsend and Tseng, 2014). Local delivery of indomethacin appears to differentially affect white fat depending on the depot since the expression of browning markers was increased in eWAT but decreased in iWAT by the indomethacin treatment in this study. At this point, this depot-related difference in white fat browning in response to indomethacin is not well understood. Studies have shown that more beige adipocytes were formed in eWAT than in iWAT in response to some drugs/nutrients, such as β 3-agonist CL316,243 (Warner et al., 2016) and retinaldehyde (Kiefer et al., 2012). We speculate that the concentrations of indomethacin reached in eWAT and iWAT may be different, resulting in different responses in indomethacin-targeted signaling events. For example, Lehmann et al. (1997) suggested that indomethacin at low concentrations may block COX activity but without activating PPAR γ ; however, at high concentrations (micromolar range) it may function as both a COX inhibitor and PPAR γ agonist. Therefore, it is possible that indomethacin, depending on its concentrations in particular tissues, would differentially affect the signaling molecules generated from both COX and PPAR γ pathways in the affected locations. Since COX-2 is required for recruitment of beige cells in WAT (Vegiopoulos et al., 2010), inhibition of COX-2 by indomethacin may lead to suppression of UCP1, which may well explain the lower expression of those browning markers in iWAT measured in our indomethacin-treated mice. Of note, a recent study showed that subcutaneous injection of indomethacin (2.5 mg/kg of body weight) suppressed cold-induced UCP1 gene expression in iWAT of C57BL/6 mice (Madsen et al., 2010).

We also found that indomethacin significantly decreased fasting blood glucose concentrations. In contrast to our results, Fjære et al. (2014) reported that indomethacin treatment (16 mg/kg of diet) prevented high-fat/high-sucrose induced obesity but deteriorated glucose intolerance in C57BL/6J mice; the different results could be explained by differences in the study design, such as the timing of indomethacin administration, diets, indomethacin doses, and delivery routes between two studies. It is worth pointing out that the increased concentrations of plasma glucose by oral delivery of indomethacin found in the Fjære et al. (2014) study was thought to be due to increased liver gluconeogenesis and impaired high-fat/high-sucrose induced glucose-stimulated insulin secretion, which is the possible consequence of systemic side effects of indomethacin. The decreased fasting blood glucose concentrations can be explained by the fact that local delivery of indomethacin might only induce the differentiation of BAT, not WAT. Activated BAT can take up and burn more circulating glucose (Townsend and Tseng, 2014). Emerging evidence suggests that BAT might protect against obesity and type-2 diabetes through BAT-derived endocrine factors (i.e., batokines) that act in a paracrine or autocrine manner (Townsend and Tseng, 2012). Therefore, indomethacin may stimulate the release of batokines, such as Fibroblast growth factor 21, interleukin-6, and neuregulin 4 (Villarroya et al., 2013, 2017), which might in turn contribute to activation of iBAT and lowered blood glucose concentrations. Future studies are needed to examine the effects of indomethacin on the release of batokines.

We recognize that the relatively small sample size is a limitation in this study. However, our animal pilot study does

support the findings from our in vitro studies showing that indomethacin promoted brown adipocyte differentiation and enhanced gene expression of brown adipocyte specific markers in the iBAT. More animal studies are required to confirm our findings and to investigate additional underlying mechanisms of indomethacin in regulating brown adipocyte differentiation and activity. Another limitation is the DIO mouse model. Mice and humans differ significantly in terms of morphometry, physiology, and life history (Lai et al., 2014). For example, since mice are significantly smaller than humans, their basal metabolic rate is seven times greater than that of humans (Demetrius, 2005). Nevertheless, these DIO mice are believed to be the best choice for investigating novel anti-obesity drugs because they better mimic human obesity than most of the genetically modified models (Lutz and Woods, 2012).

In conclusion, the present studies demonstrated that indomethacin, a commonly used nonsteroidal anti-inflammatory drug, promoted mouse brown adipocyte differentiation in vitro. Local delivery of indomethacin to iBAT improved hyperglycemia, and increased brown fat thermogenesis capacity in DIO mice. Our studies highlighted the advantages of local or targeted BAT delivery of indomethacin to maximize its beneficial effects on promoting brown adipogenesis and to minimize its toxic side effects often associated with systemic delivery to WAT (increased white adipogenesis) and the liver (increased gluconeogenesis).

Acknowledgments

We thank Yujiao Zu, Jie Liu, and Md Shahjalal Khan for help in the animal study.

Authorship Contributions

Participated in research design: Hao, Kearns, Zhao, Wang.
Conducted experiments: Hao, Kearns, Zhao, Wang, Scott, Wu.
Performed data analysis: Hao, Kearns, Sun, Zhao, Wang, Scott, Wu.
Wrote or contributed to the writing of the manuscript: Hao, Kearns, Zhao, Wang, Scott, Wu, Kodani, Morisseau, Hammock.
