Received October 11, 2018; accepted December 19, 2018

ABSTRACT

Checkpoint blockade therapy has been proven efficacious in lung cancer patients. However, primary/acquired resistance hampers its efficacy. Therefore, there is an urgent need to develop novel strategies to improve checkpoint blockade therapy. Here we tested whether dual inhibition of cyclooxygenase-2 (COX-2) and epidermal growth factor receptor (EGFR) by flavonoid melafolone improves program death 1 (PD-1) checkpoint blockade therapy through normalizing tumor vasculature and PD-1 ligand (PD-L1) downregulation. Virtual screening assay, cellular thermal shift assay, and enzyme inhibition assay identified melafolone as a potential inhibitor of COX-2 and EGFR. In Lewis lung carcinoma (LLC) and CMT167 models, dual inhibition of COX-2 and EGFR by melafolone promoted survival, tumor growth inhibition, and vascular normalization, and ameliorated CD8⁺ T-cell suppression,

accompanied by the downregulation of transforming growth factor- β (TGF- β), vascular endothelial growth factor (VEGF), and PD-L1 in the tumor cells. Mechanistically, dual inhibition of COX-2 and EGFR in lung cancer cells by melafolone increased the migration of pericyte, decreased the proliferation and migration of endothelial cells, and enhanced the proliferation and effector function of CD8⁺ T cells through VEGF, TGF- β , or PD-L1 downregulation and PI3K/AKT inactivation. Notably, melafolone improved PD-1 immunotherapy against LLC and CMT167 tumors. Together, dual inhibition of COX-2 and EGFR by melafolone improves checkpoint blockade therapy through vascular normalization and PD-L1 downregulation and, by affecting vessels and immune cells, may be a promising combination strategy for the treatment of human lung cancer.

Introduction

Lung cancer remains one of the leading causes of cancer mortality in the world (Siegel et al., 2016). Even after maximal safe resection and chemoradiation, the 5-year survival rate is dismal (Raju et al., 2018). Checkpoint blockade therapy, including monoclonal antibodies against programmed cell death 1 (PD-1) and its ligand (PD-L1), is a breakthrough for multiple types of cancer, including non-small cell lung cancer (NSCLC) (Meyers et al., 2018). Unfortunately, a significant subset of patients does not respond to immunotherapy and another subset eventually develops resistance

after the initial response (O'Donnell et al., 2017). Thus, it is of great importance to develop novel strategies to improve checkpoint blockade therapy for lung cancer.

The infiltration of cytotoxic CD8⁺ T lymphocytes in tumors is a prerequisite for successful cancer immunotherapy (Chowdhury et al., 2018). However, high abnormalization of tumor blood vessels hinders the CD8⁺ T-cell infiltration into tumor parenchyma and thus promotes tumor escape from immune attack (Wallin et al., 2016). Moreover, the abnormal tumor vasculature establishes a hypoxic microenvironment that induces immune regulatory proteins such as PD-1 and PD-L1 (Siemann and Horsman, 2015; Ruf et al., 2016). The PD-L1/PD-1 upregulation suppresses CD8⁺ T-lymphocyte activation and proliferation, and thereby promotes the progression of solid tumors (Chen et al., 2015). Conversely, tumor vessel normalization with low-dose tumor necrosis factor- α substantially promotes the infiltration of CD8⁺ T lymphocytes and thereby improves antitumor vaccination or adoptive T-cell therapy in

ABBREVIATIONS: CFSE, carboxyfluorescein succinimidyl ester; CM, conditioned media; COX-2, cyclooxygenase-2; EGFR, epidermal growth factor receptor; ELISA enzyme-linked immunosorbent assay; EP4, prostaglandin E2 receptor 4; GzmB, granzyme B; IFN- γ , interferon- γ ; IL-2, interleukin-2; LLC, Lewis lung carcinoma; Mel, melafolone, 2-methyl-butiric acid 2,4-dihydroxy-3,6-dimethoxy-5-[(E)-(3-phenyl-acryloyl)]-phenyl ester; NSCLC, non-small cell lung cancer; PD-1, programmed cell death 1; PD-L1, programmed cell death ligand 1; PGE₂, prostaglandin E₂; TAMs, tumor-associated macrophages; TGF- β , transforming growth factor- β ; VEGF, vascular endothelial growth factor.

a preclinical model of insulinoma (Johansson et al., 2012). Normalization of tumor vasculature also enhanced extravasation of adoptively transferred T cells into tumors and improved adoptive cell transfer-based immunotherapy in B16 melanoma (Shrimali et al., 2010). However, whether tumor vascular normalization improves the anti-PD-1 immunotherapy for lung cancer has not been elucidated.

Cyclooxygenase-2 (COX-2) and its metabolite prostaglandin E_2 (PGE₂) upregulate PD-L1 in myeloid-derived suppressor cells and tumor-associated macrophages (TAMs) in murine MBT-2 bladder tumor (Prima et al., 2017). COX-2 expression is correlated with PD-L1 expression in resected tissue specimens of human lung adenocarcinoma (Shimizu et al., 2017). However, COX-2 inhibition had no impact on PD-L1 expression in the in vitro cultured NSCLC cells (Shimizu et al., 2018), suggesting that single blockade of COX-2 pathway may be insufficient to modulate PD-L1 in NSCLC. Epidermal growth factor receptor (EGFR) is frequently overexpressed in human lung cancers and correlates with poor patient outcome (Selvaggi et al., 2004; Arfaoui et al., 2014; Gately et al., 2014). The oncogenic EGFR signaling upregulates PD-L1 in lung cancer, whereas EGFR inhibition downregulates PD-L1 in NSCLC (Wang et al., 2017b; Li et al., 2018). Increasing evidence demonstrates that interactions between EGFR and COX-2 pathways affect tumor growth, angiogenesis, and metastasis in lung cancer (Li et al., 2016; Shi et al., 2017). Dual EGFR and COX-2 inhibition exerts additive antitumor growth and antiangiogenesis effects in lung cancer (Li et al., 2016). However, whether dual EGFR and COX-2 inhibition expands the benefit of anti-PD-1 immunotherapy in lung cancer is largely unknown.

There is growing interest in exploring dietary flavonoids as antitumor immunity candidates (Lewandowska et al., 2016; Takac et al., 2018). We previously reported that flavonoid CH625 normalizes vasculature while accompanied by increased antitumor immunity in C6 and GL261 gliomas (Wang et al., 2018). A recent study from another group demonstrated that flavone apigenin suppresses expression of PD-L1 and enhances proliferation of T cells in breast cancer (Coombs et al., 2016). However, whether the flavonoid improves the anti-PD-1 checkpoint blockade therapy has not been investigated. In this study, we demonstrated that melafolone (Mel, 2-methyl-butyric acid 2,4-dihydroxy-3,6-dimethoxy-5-[(E)-(3-phenyl-acryloyl)]-phenyl ester), one of the pharmacologically active flavonoids from *Polygonum lapathifolium*, improves anti-PD-1 immunotherapy through vascular normalization and PD-L1 downregulation via a COX-2 and EGFR-dependent mechanism. Our results may lead to a potential combination strategy to facilitate checkpoint blockade therapy in human lung cancer.

Materials and Methods

Plant Material and Mel Preparation. In this study, the root of *Polygonum lapathifolium* collected in Yili Prefecture, Xinjiang Province, China, was authenticated by Dr. Mingxi Jiang from Wuhan Institute of Botany, Chinese Academy of Sciences. The Mel was isolated, purified, and identified according to a previously described method (Ezhilan and Neelamegam, 2012). The purity of Mel measured by high-performance liquid chromatography was higher than 99%. For in vivo studies, liposomal Mel was made by mixing cholesterol, 1,2-dimyristoyl-sn-glycero-3-phosphocholine and Mel at a mole ratio of 5:5:1, according to previously described method (Wang et al., 2018).

For in vitro studies, Mel was dissolved in dimethyl sulfoxide as a stock solution (80 mM), stored at -20°C , and the serial dilution was performed in cell culture medium (final dimethyl sulfoxide concentration $\leq 1\%$).

Cell Culture and Lentiviral Transduction. The human A549 lung cancer cells, mouse Lewis lung carcinoma (LLC) cells, mouse endothelial cells MS1, mouse pericyte-like cell 10T1/2, and human umbilical vein endothelial cells (HUVEC) were obtained from the American Type Culture Collection (ATCC, Manassas, VA). Murine CMT167 lung cancer cell line was purchased from the Cancer Research UK Central Cell Service (Clare Hall, Middlesex, UK). Human CD8⁺ T cells were isolated from the blood of healthy volunteers in accordance with the Helsinki Declaration. All volunteers gave written informed consent, and the experiment was approved by the Institutional Review Board of the Wuhan University. Mouse tumor cells and CD8⁺ T cells were isolated and purified from tumors with a mouse tumor cell or CD8⁺ T-cell isolation kit (Miltenyi Biotec, Auburn, CA). The cells were grown in RPMI 1640 or Dulbecco's modified Eagle's medium with 10% fetal bovine serum in the humidified incubator. Mycoplasma testing for all cell lines was performed every 3 months using the MycoAlert Mycoplasma Detection Kit (Lonza, Slough, UK).

LLC and A549 cells were placed in a six-well tissue culture plate at the density of 2×10^5 . Cells at 80% confluence in the plate were transduced with COX-2, PD-L1, or Akt lentiviral activation particles (Santa Cruz Biotechnology) for 24 hours. The negative control lentivirus was transduced in the cells as control. The protein expression COX-2, PD-L1, and Akt was determined by Western blot.

Molecular Docking Study. Structure-based virtual screening was performed in accordance with a previously described method (Sogabe et al., 2012; Liu et al., 2018). Briefly, human EGFR (PDB id: 3W2S) and COX-2 (PDB id: 5IKT) crystal structures were obtained from the protein data bank (PDB). The active sites were defined by the cocrystallized inhibitors of the COX-2 and EGFR. The candidates were filtered by Lipinski's rule of five utilizing SYBYL-X 2.0 (Tripos, St. Louis, MO). The SYBYL software was used to assign the standard Assisted Model Building with Energy Refinement (AMBER) atomic partial charges on the COX-2 and EGFR proteins and the Gasteiger-Hückel atomic partial charges on the ligand candidates to be docked. After these procedures, the docking was carried out in SYBYL software under default setting, and the figures were obtained by utilizing PyMol (<http://www.pymol.org>).

Cellular Thermal Shift Assay. Cellular thermal shift assay (CETSA) was conducted using cell lysates as previously described (Dai et al., 2018). For the temperature-dependent thermal shift assay, 50 μl of lysates (3 mg/ml) from A549 cells were incubated with 20 μM of Mel at each temperature point from 36°C to 80°C for 4 minutes. The supernatant and pellet were separated from the above samples by centrifugation at 20,000g for 10 minutes. Twelve microliters of the supernatant was mixed with 3 μl of $5 \times$ loading buffer and then separated on a 10% SDS-PAGE for immunoblotting analysis of COX-2 or EGFR. For the dose-dependent thermal shift assay, 50 μl of lysates (3 mg/ml) were incubated with various concentrations of Mel (between 0.001 and 1000 μM) at 52°C for 4 minutes. Supernatants were isolated by centrifugation and subjected to immunoblotting analysis of COX-2 or EGFR as described above.

Tumor Model and Treatment Regimen. C57BL/6 mice (male, 6–8 weeks old, 16–20 g) were provided by the Center for Disease Control and Prevention (Hubei, China). The mice were housed in the pathogen-free environment on a 12-hour dark and 12-hour light cycle with ad libitum access to water and food. The animal experiments were carried out in accordance with the guidelines of the animal ethics committee of the Animal Research Committee of Wuhan University.

In the LLC or CMT167 subcutaneous tumor model, LLC (2×10^5) or CMT167 (2×10^5) cells were subcutaneously injected in the right flank of C57BL/6 mice. Seven days later when the tumors had reached a size of about 100 mm³, the mice were intraperitoneally administered Mel (20 and 40 mg/kg daily) or vehicle. The dose of Mel was selected

according to the preliminary experiments. For the combination experiments, mice were administered anti-PD-1 antibody (cat. no. BE0146; Bio X Cell, West Lebanon, NH; 200 μ g/mouse every 3 days, i.p.), Mel (20 mg/kg daily, i.p.), anti-PD-1 antibody plus Mel, or vehicle. The dose of anti-PD-1 antibody was selected according to previous study (Tan et al., 2018). One-half of the mice in the LLC or CMT167 models were sacrificed on day 15 or day 21 after tumor implantation, and the tumor tissues and the peripheral blood were collected and analyzed. The remaining mice were used for the survival study. Mice were sacrificed when they became moribund or when the tumor length reached 2 cm. Survival was assessed from the 1st day of implantation until death.

Tumor Perfusion Measurement. Laser Doppler analysis of tumor perfusion was carried out according to previously described method (Wang et al., 2018). Briefly, 0.6% pentobarbital was used to anesthetize the LLC tumor-bearing mice described above. We then placed the mice on the 37°C heating pad and carefully excised the skin capsule over the tumor to protect the vascular network. Tumor perfusion in mice administered Mel or vehicle at days 0, 2, 4, 6, and 8 was blindly determined by utilizing the laser Doppler analyzer (LDPI; Moor Instruments, Axminster, UK). The tumor perfusion in arbitrary perfusion units was monitored graphically.

Analysis for Serum Biochemical Parameters. The peripheral blood from the mice administered anti-PD-1 antibody (200 μ g/mouse), Mel (20 mg/kg), anti-PD-1 antibody plus Mel, or vehicle was collected. Complete blood counts, including red blood corpuscles, white blood corpuscles, platelet, mean cell volume, and hematocrit levels, were measured by Sysmex XE-2100 (TOA Medical Electronics, Kobe, Japan), and the blood urea nitrogen, plasma alanine aminotransferase, aspartate aminotransferase, creatine kinase-MB, and creatine levels were measured by Beckman LX20 (Beckman-Coulter, Brea, CA) according to a previous study (Li et al., 2013).

Immunofluorescence. The tumor tissues from the mice administered Mel or vehicle were incubated with anti-CD31 (1:100, ab24590; Abcam, Cambridge, MA) and anti-smooth muscle actin (1:100, ab32575; Abcam) antibodies at 4°C overnight. Tissues were then hatched with secondary antibodies conjugated with Alexa Fluor

594 or 488 for 1 hour. After a washing, the tissues were mounted with fluorescent mounting medium containing DAPI. Each section was observed by an Olympus BX51 microscope.

Western Blot Analysis. Proteins in the LLC, CMT167, A549, or human and mouse CD8⁺ T cells were extracted, and protein concentrations were measured according to the Bradford method. Protein extracts were resolved by SDS-PAGE and transferred to polyvinylidene fluoride membranes. The membranes blocked by 5% nonfat milk were probed with antibodies against EGFR (1:5000, ab52894; Abcam), p-EGFR (1:3000, ab182618; Abcam), hypoxia-induced factor (HIF)-1 α (1:1000, sc-13515; Santa Cruz Biotechnology, Dallas, TX), PD-L1 (1:1000, ab213480; Abcam), granzyme B (GzmB) (1:1000, ab53097; Abcam), IFN- γ (1:5000, ab133566; Abcam), interleukin-2 (IL-2) (1:2000, ab180780; Abcam), prostaglandin E2 receptor 4 (EP4; 1:1000, sc-55596; Santa Cruz Biotechnology), Akt (1:500, ab8805; Abcam), p-Akt (1:1000, ab38449; Abcam), or β -actin (1:3000, ab227387; Abcam) at 4°C overnight. After a washing, the blots were stained with peroxidase-conjugated antibody, and the enhanced chemiluminescence kit was used for chemiluminescence detection.

Analysis of Gene Expression. Total RNA was isolated with Trizol (Invitrogen, Carlsbad, CA), and reverse-transcribed to cDNA by a PrimeScript RT Reagent Kit with gDNA Eraser (Takara, Dalian, Liaoning, China) according to the manufacturer's protocol. The reaction of real-time PCR mixtures containing SYBR Green was composed in accordance with the manufacturer's instructions (Takara). Quantification was carried out utilizing the $2^{-\Delta\Delta C_t}$ method. The primers of vascular endothelial growth factor (VEGF), transforming growth factor- β (TGF- β), PD-L1, GzmB, IL-2 and IFN- γ were designed on the basis of previously published sequences (Allen et al., 2017; Chen et al., 2017a; Tan et al., 2018). Primers used in this study were shown in Supplemental Table 1. Target gene expression level was normalized to GAPDH (Duan et al., 2018).

Conditioned Media Preparation. The conditioned media (CM) from LLC and A549 cells was made in accordance with a previously described method (Chen et al., 2017a). Briefly, the LLC and A549 cells

Fig. 1. Binding modes of melafolone with COX-2 and EGFR. (A) Proposed molecular model of Mel binding with COX-2. Mel is shown as a yellow stick. (B) Proposed molecular model of Mel binding with EGFR. Mel is shown as a yellow stick. (C–F) The A549 cells were treated with dimethyl sulfoxide or Mel (20 μ M) with increasing temperature (36–80°C, interval temperature: 4°C) or drug concentration at 52°C. (C and D) The thermal stability of COX-2 in cell lysates was measured by the temperature or concentration-dependent CETSA. (E and F) The thermal stability of EGFR in cell lysates was measured by the temperature or concentration-dependent CETSA. Each value represents the mean $\pm$ S.E.M. of five independent triplicate experiments. * P < 0.05; ** P < 0.01 vs. control.

in six-well plates were administered Mel (10 and 20 μ M) or vehicle for 24 hours. The cell supernatants from the above-treated cells were then centrifuged and filtered through an Amicon Ultra-4 filter to exclude the trace of Mel. The retentate was gathered as CM.

Enzyme-Linked Immunosorbent Assay. TGF- β , VEGF, or PGE₂ levels in the LLC and CMT167 cells isolated from the Mel (20 and 40 mg/kg)-treated LLC and CMT167 tumors and the culture supernatants from Mel (10 and 20 μ M)-treated LLC and A549 cells were determined using enzyme-linked immunosorbent assay (ELISA) kits. IFN- γ , GzmB, and IL-2 in the CD8⁺ T cells isolated from the Mel-treated LLC and CMT167 tumors and the culture supernatants from the human and mouse CD8⁺ T cells were determined by ELISA kits (R&D Systems, Minneapolis, MN).

Flow Cytometry. T cells were stained with FITC-labeled anti-CD8 antibody and allophycocyanin (APC)-labeled anti-CD3 antibody (BD Biosciences, San Jose, CA). FACS data were obtained on the FACS Aria III flow cytometer and evaluated by utilizing the FlowJo software (Tree Star, Ashland, OR). The proliferation of CD8⁺ T cells was measured by flow cytometry in accordance with the manufacturer's instructions (BD Biosciences). Plate-bound anti-CD28 antibody and anti-CD3 antibody were used to stimulate T cells. After stimulation, the T cells were treated with the CM from LLC and A549 cells for 24, 48, and 72 hours. CD8⁺ T cells were determined by carboxyfluorescein succinimidyl ester (CFSE) dilution.

Cell Proliferation Assay. The cell proliferation assay was carried out according to a method described previously (Wang et al., 2017a). LLC and A549 cells were placed in 96-well plates at a density of 1×10^4 /well. The cells were collected after exposure to serial concentrations of Mel for 24 hours. Cell viability was measured by MTS (CellTiter 96 Aqueous Assay reagent; Promega, Madison, WI) in accordance with the manufacturer's protocol. 5-Bromo-2'-deoxyuridine (BrdU) incorporation was measured with a cell proliferation ELISA kit (Roche Diagnostics, Indianapolis, IN) in accordance with the manufacturer's instructions. HUVEC or MS1 (1×10^4 /well) seeded in 96-well plates was incubated with the CM from LLC or A549 cells for

24 hours. The cell viability was determined in accordance with the instruction of MTS.

Migration Assay. The migration assay was carried out in accordance with a method described previously (Wang et al., 2018). Human brain vascular pericytes (HBVP), 10T1/2, HUVEC, or MS1 (1×10^4 /well) were placed in the upper chamber, and 0.6 ml CM from LLC or A549 cells was placed in lower chamber. The nonmigrated cells in the upper chamber were removed. The cells migrating through the pores to the lower chamber were fixed and stained with 0.1% crystal violet blue. The stained cells in the lower chamber were counted.

Statistical Analysis. The Kolmogorov-Smirnov test was used to evaluate normal distribution of the data. Normal distributed data were then tested by one-way analysis of variance (ANOVA) followed by two-tailed Student's *t* test or Student-Newman-Keul's test. One-way repeated measures ANOVA and Bonferroni's post-hoc test were performed to evaluate the statistical significance of changes over time. The Kaplan-Meier method and the log-rank test were used to estimate the survival rates. Data are presented as mean $\pm$ S.E.M., and *P* values of 0.05 or less were regarded as statistically significant.

Results

Mel is a Potential Inhibitor of COX-2 and EGFR. To explore the potential application of COX-2 and EGFR as drug targets, traditional Chinese medicine database (TCM Database@Taiwan) was used to perform virtual screening. We narrowed our focus from the 36,043 total compounds to the 15 top flavonoids as potential COX-2 and EGFR inhibitors (Supplemental Table 2). Among the 15 hits, Mel (ZINC14640449) showed strong interaction with COX-2 and EGFR with the docking energies of 5.52 and 9.92, respectively. COX-2/EGFR inhibitors interact with TYR355 and ALA527 of COX-2 and PHE856 of EGFR (Blobaum and

Fig. 2. Melafolone prolongs survival and delays tumor growth in Lewis lung carcinoma and CMT167 tumors. (A) LLC (2×10^5) were injected subcutaneously into the right flank of C57BL/6 mice. When tumors had reached a size of about 100 mm³, Mel was administered intraperitoneally at a dose of 20 and 40 mg/kg in mice once daily for 7 days. Tumor weight was measured in the LLC model. (B) CMT167 cells (2×10^5) were injected subcutaneously into the right flank of C57BL/6 mice. When tumors had reached a size of about 100 mm³, Mel was administered intraperitoneally at the dose of 20 and 40 mg/kg in mice once daily for 14 days. Tumor weight was measured in the CMT167 model. (C and D) The survival time of the mice treated with Mel (20 and 40 mg/kg) or vehicle was determined by ELISA. (E) PGE₂ in the tumor cells from the LLC and CMT167 tumors treated with Mel (20 and 40 mg/kg) or vehicle was determined by ELISA. (F) p-EGFR and EGFR in the tumor cells from the LLC and CMT167 tumors by Western blot. The values are presented as the mean $\pm$ S.E.M., *n* = 8, **P* < 0.05; ***P* < 0.01 vs. control.

Marnett, 2007; Li et al., 2012; Alanazi et al., 2015). We demonstrated that Mel formed a hydrophobic interaction with the key catalytic-site residue TYR355 and interacted with the ALA527 of COX-2 through a hydrogen bond (H-bond) (Fig. 1A). Mel formed H-bonds with LYS745 and ASP837 and had a lipophilic interaction with PHE856 of EGFR (Fig. 1B). To further validate the binding of Mel to Cox-2 and EGFR, we

performed the CETSA in human A549 cells. The thermal stability of human EGFR and COX-2 in the Mel-treated A549 cells was enhanced with increased temperatures (36°C–80°C) and Mel concentration (0.001–1000 μ M) (Fig. 1, C–F), suggesting a direct interaction between Mel and human COX-2 or EGFR. Previous studies had shown that human EGFR and mouse EGFR are highly homologous (Ebben et al., 2016;

Fig. 3. Melafolone promotes vascular normalization in Lewis lung carcinoma and CMT167 tumors. LLC (2×10^5) or CMT167 cells (2×10^5) were injected subcutaneously into the right flank of C57BL/6 mice. When tumors had reached a size of about 100 mm³, Mel was administered intraperitoneally at the dose of 20 and 40 mg/kg in mice once daily for 7 or 14 days, respectively. Fig. 4. Melafolone downregulates PD-L1 and enhances the infiltration and effector function of CD8⁺ T cells in the Lewis lung carcinoma and CMT167 tumors. (A) PD-L1 in tumor cells from the LLC and CMT 167 tumors treated with Mel (20 and 40 mg/kg) or vehicle was determined by Western blot. (B) The number of CD8⁺ T cells in the LLC and CMT167 tumors treated with Mel (20 and 40 mg/kg) or vehicle was determined by flow cytometry. (C and D) GzmB, IFN-γ, and IL-2 in the CD8⁺ T cells from the LLC tumors were determined by quantitative PCR and Western blot. (E and F) GzmB, IFN-γ, and IL-2 in the CD8⁺ T cells from the CMT167 tumors were determined by quantitative PCR and Western blot. The values are presented as the mean ± S.E.M., *n* = 8, **P* < 0.05; ***P* < 0.01 vs. control.

Kikuchi et al., 2016). We found that the human and mouse EGFR have 92% query coverage and 90% identity, and the human and mouse COX-2 have 97% query coverage and 87% identity according to NCBI Protein BLAST. The thermal stability of mouse EGFR and COX-2 in the Mel-treated LLC cells was also enhanced compared with the control (Supplemental Fig. 1). Furthermore, we found that Mel inhibited COX-2-catalyzed PGE₂ production, with an IC₅₀ value of 13.2 μM, and EGFR phosphorylation, with the IC₅₀ value of 17.4 μM, in A549 cells. Enzyme kinetic analysis showed that Mel is a competitive inhibitor of COX-2, since the *K_m* value was enhanced but the *V_{max}* was unchanged (Supplemental Fig. 2). Together, these results indicate that Mel is a potential inhibitor of COX-2 and EGFR.

Mel Prolongs Survival and Delays Tumor Growth in the LLC and CMT167 Tumors. The mice bearing subcutaneous LLC and CMT167 tumors were administered Mel

(20 and 40 mg/kg) or vehicle. We found that Mel 40 mg/kg significantly reduced LLC and CMT167 tumor weight but Mel 20 mg/kg did not (Fig. 2, A and B). Mel (20 and 40 mg/kg) significantly increased survival in the LLC or CMT167-bearing mice compared with control mice (Fig. 2, C and D). Furthermore, Mel (20 and 40 mg/kg) decreased the level of PGE₂ and p-EGFR in tumor cells from LLC and CMT167 tumors without influencing EGFR (Fig. 2, E and F). These data indicate that Mel prolongs survival and delays tumor growth in the LLC and CMT167 tumors.

Mel Promotes Vascular Normalization and Ameliorates CD8⁺ T-Cell Suppression in LLC and CMT167 Tumors. Previous studies showed that normalization of tumor vasculature delays tumor growth, and functional normalization is an essential element in the vascular normalization paradigm (Qin et al., 2015). Thus, we used laser Doppler

Fig. 5. Melafolone blocks VEGF, TGF- β , and PD-L1 production through the downregulation of COX-2 and EGFR in lung cancer cells. (A) PGE₂ in culture supernatants from the Mel (10 and 20 μ M) or vehicle-treated Lewis lung carcinoma and A549 cells were determined by ELISA. (B) p-EGFR and EGFR in the LLC and A549 cells treated with Mel (10 and 20 μ M) or vehicle for 24 hours were determined by Western blot. (C and D) VEGF and TGF- β in culture supernatants was determined by ELISA. (E) PD-L1 in the LLC and A549 cells treated as described in Fig. 5B was measured by quantitative PCR. (F) The effects of COX-2 overexpression on COX-2 protein levels in LLC and A549 cells were measured by Western blot. Each value represents the mean $\pm$ S.E.M. of five independent triplicate experiments. * P < 0.05; ** P < 0.01 vs. negative control lentivirus (LV-NC). (G) Parental and COX-2^{high} LLC and A549 cells were treated with Mel (20 μ M) or vehicle for 24 hours, followed by treatment with or without PGE₂ (1 μ M) or EGF (20 ng/ml) for another 24 hours. VEGF and TGF- β in culture supernatants were determined by ELISA. (H) PD-L1 in the LLC and A549 cells treated as described in Fig. 5G was measured by Western blot. Each value represents the mean $\pm$ S.E.M. of five independent triplicate experiments. * P < 0.05; ** P < 0.01 vs. control, # P < 0.05; ## P < vs. Mel (20 μ M)-treated group.

analysis to measure the tumor perfusion. As shown in Fig. 3A, Mel (20 and 40 mg/kg) notably enhanced LLC tumor perfusion compared with the control. Tumor perfusion in the control mice rose by 4.5% at day 2, and rose higher, by 9.7%, at day 4, and increased slightly by 5.0% at day 8 compared with tumor perfusion measured at day 0. Mel (20 and 40 mg/kg) steadily increased tumor perfusion until day 4 (25.6% and 34.0%, respectively), and increased tumor perfusion slightly at day 8 (15.7% and 19.4%, respectively) compared with tumor perfusion measured at day 0. However, tumor perfusion measured at day 8 showed a rapid decline when compared with that measured at day 4. These data indicate that Mel could create a short-lived time window of about 5 days when tumor vessels could normalize transiently. We then double-stained the pericyte marker α -smooth muscle actin (α -SMA) and the endothelial cell marker CD31 and found that Mel (20 and 40 mg/kg) reduced microvessel density but enhanced vessel pericyte coverage in LLC and CMT167 tumors (Fig. 3, B–G). Furthermore, the expression of HIF-1 α was significantly decreased in response to Mel (Fig. 3H). We also observed the downregulated TGF- β and VEGF in the tumor cells from LLC and CMT167 tumors by Mel treatment (Fig. 3I). These data suggest that Mel promotes vascular normalization in the LLC and CMT167 tumors.

Next, we measured the effects of Mel on CD8⁺ T-cell suppression in LLC and CMT167 tumors. As shown in Fig. 4, A and B, Mel (20 and 40 mg) significantly reduced the expression of PD-L1 in the tumor cells and enhanced the number of CD8⁺ T cells in LLC and CMT167 tumors. We then examined the effector function of CD8⁺ T cells upon Mel treatment and found that Mel increased the expression of GzmB, IL-2, and IFN- γ (Fig. 4, C–F). These results indicate that Mel downregulates PD-L1 in tumor cells and enhances the infiltration and effector function of CD8⁺ T cells in LLC and CMT167 tumors.

Mel Downregulates VEGF, TGF- β , and PD-L1 in Lung Cancer Cells through COX-2 and EGFR Inhibition. We investigated next whether Mel downregulated VEGF, TGF- β , and PD-L1 in lung cancer cells through both COX-2 and EGFR inhibition. We found that Mel (10 and 20 μ M) did not affect the proliferation of mouse LLC and human A549 lung cancer cells (Supplementary Fig. 3) but decreased the level of PGE₂ and p-EGFR with the downregulated VEGF, TGF- β , and PD-L1 in the LLC and A549 cells (Fig. 5, A–E). By contrast, overexpression of COX-2 or exogenous addition of PGE₂ or EGF attenuated these effects (Fig. 5, F–H). These data suggest that Mel downregulated tumor cell-derived VEGF, TGF- β , and PD-L1 through COX-2 and EGFR inhibition.

Fig. 6. COX-2 and EGFR inhibition by melafolone increases the migration of pericyte cells and decreases the proliferation and migration of endothelial cells through downregulation of VEGF and TGF- β . (A and B) Lewis lung carcinoma and A549 cells were treated with Mel (10 and 20 μ M) or vehicle for 24 hours. The condition medium from each group was added to the lower chamber. Pericyte cells (mouse pericyte-like cells, 10T1/2, and human brain vascular pericytes, HBVP) (A) or endothelial cells (mouse endothelial cells, MS1, and human umbilical vein endothelial cells, HUVEC) (B) were added to the upper chamber and then incubated overnight. The cells that migrated to the lower chamber were counted. MS1 or HUVEC was plated at 1×10^4 per well in 96-well culture plates and then treated with the CM. Cell proliferation was measured using MTS assays (B). (C and D) Parental and COX-2^{high} LLC and A549 cells were treated with Mel (20 μ M) or vehicle for 24 hours, followed by treatment with or without PGE₂ (1 μ M), EGF (20 ng/ml), VEGF (20 ng/ml), or TGF- β (10 ng/ml) for another 24 hours. The CM from each group was added to the lower chamber. Pericyte cells (10T1/2 and HBVP) (C) or endothelial cells (MS1 and HUVEC) (D) were added to the upper chamber and then incubated overnight. The cells that migrated to the lower chamber were counted. MS1 or HUVEC were plated at 1×10^4 per well in 96-well culture plates and then treated with the CM. Cell proliferation was measured using MTS assays (D). Each value represents the mean $\pm$ S.E.M. of five independent triplicate experiments. * $P < 0.05$; ** $P < 0.01$ vs. control, # $P < 0.05$; ### $P < 0.01$ vs. Mel (20 μ M)-treated group.

COX-2 and EGFR Inhibition by Mel Enhances the Migration of Pericyte Cells and Reduces the Proliferation and Migration of Endothelial Cells through VEGF and TGF- β Downregulation. Inhibition of TGF- β and VEGF derived from tumor cells contributes to tumor vessel normalization (Joseph et al., 2013; Wouters et al., 2013). We demonstrated that the CM from Mel (10 and 20 μ M)-treated lung cancer cells increased pericyte cell migration and reduced endothelial cell proliferation and migration (Fig. 6, A and B). However, overexpression of COX-2 and exogenous addition of PGE₂, EGF, TGF- β , or VEGF attenuated these effects (Fig. 6, C and D). These data indicate that COX-2 and EGFR inhibition by Mel in lung cancer cells enhanced the migration of pericyte cells and reduced the proliferation and migration of endothelial cells through the downregulation of VEGF and TGF- β .

COX-2 and EGFR Inhibition by Mel Increases the Proliferation and Effector Function of CD8⁺ T Cells through PD-L1 Downregulation. Because PD-L1 in tumor cells induces CD8⁺ T-cell anergy and exhaustion (Ramjiawan et al., 2017), we sought to determine whether Mel ameliorates CD8⁺ T-cell suppression via PD-L1 regulation. We observed enhanced proliferation of CD8⁺ T cells and expression of its effector cytokine GzmB, IFN- γ , and IL-2 when Mel-treated LLC and A549 cells were cocultured with CD8⁺ T cells (Fig. 7,

A and B). By contrast, overexpression of COX-2 or PD-L1 and exogenous addition of EGF or PGE₂ partially reversed these effects (Fig. 7, C and D). These results indicate that COX-2 and EGFR inhibition by Mel increases the proliferation and effector function of CD8⁺ T cells through PD-L1 downregulation.

PI3K/Akt Signal Contributes to Mel-Mediated VEGF, TGF- β , and PD-L1 Downregulation. We found that Mel (10 and 20 μ M) reduced EP4 expression and Akt phosphorylation in the A549 cells (Fig. 8A). Conversely, overexpression of COX-2 or exogenous addition of PGE₂ or EGF attenuated the effect of Mel on Akt phosphorylation (Fig. 8B). To study whether Mel downregulates VEGF, TGF- β , and PD-L1 via PI3K/Akt, we overexpressed Akt in the A549 cells (Fig. 8C). As shown in Fig. 8, D and E, Akt overexpression reversed Mel (20 μ M)-induced upregulation of TGF- β , VEGF, and PD-L1 in A549 cells. The CM from the Mel (20 μ M)-treated A549 cells enhanced pericyte cell migration and reduced endothelial cell proliferation and migration, which was reversed by Akt overexpression (Fig. 8, F–H). Of note, Akt overexpression partially reversed Mel (20 μ M)-induced increase in CD8⁺ T-cell number and production of GzmB, IL-2, and IFN- γ (Fig. 8, I and J). These data suggest that Mel downregulates VEGF, TGF- β , and PD-L1 in lung cancer cells mainly via PI3K/Akt signal.

COX-2 and EGFR Inhibition by Mel Improves Anti-PD-1 Immunotherapy. We next studied whether dual COX-2

Fig. 7. COX-2 and EGFR inhibition by Mel increases the proliferation and effector function of CD8⁺ T cells through downregulation of PD-L1. (A and B) The CD8⁺ T cells were stimulated with 2 μ g/ml plate-bound anti-CD3 and anti-CD28 antibodies for 24 hours, and then cocultured with Mel (10 and 20 μ M)-treated LLC and A549 cells for the indicated time. (A) The proliferation of CD8⁺ T cells was measured by CFSE dilution. (B) Production of GzmB, IFN- γ and IL-2 in CD8⁺ T cells was determined by ELISA. (C and D) Parental and COX-2^{high} or PD-L1^{high} LLC cells and human A549 lung cancer cells were treated with Mel (10 and 20 μ M) or vehicle for 24 hours, followed by treatment with or without PGE₂ (1 μ M) or EGF (20 ng/ml) for another 24 hours. (C) The CD8⁺ T cells were stimulated with 2 μ g/ml plate-bound anti-CD3 and anti-CD28 antibodies for 24 hours, and then cocultured with the LLC and A549 cells for the indicated time. The proliferation of CD8⁺ T cells was measured by CFSE dilution. (D) Production of GzmB, IFN- γ , and IL-2 in CD8⁺ T cells was determined by ELISA. Each value represents the mean $\pm$ S.E.M. of five independent triplicate experiments. * P < 0.05; ** P < 0.01 vs. control, # P < 0.05; ## P < vs. Mel (20 μ M)-treated group.

and EGFR inhibition by Mel improves PD-1 blockade immunotherapy in LLC and CMT167 tumors. As with previous reports (Lin et al., 2018; Tan et al., 2018), LLC tumors were resistant to anti-PD-1 immunotherapy (Fig. 9, A and B). Combined Mel with anti-PD-1 treatment greatly reduced tumor weight and prolonged survival compared with the anti-PD-1 therapy (Fig. 9, A and B). In the CMT167 model, tumors were notably restrained, and survival of mice was extended by anti-PD-1 therapy (Fig. 9, C and D). Mel synergized with PD-1 antibody in restraining tumor growth (Fig. 9C) and prolonging survival (Fig. 9D). Compared with the anti-PD-1 monotherapy, the combination of Mel treatment and PD-1 blockade decreased the production of PGE₂ and phosphorylation of EGFR and AKT with the down-regulated VEGF, TGF- β , and PD-L1 in the tumor cells from the A549 and LLC tumors (Fig. 9, E–I). The combination arms also reduced microvessel density, enhanced vessel pericyte coverage, and increased the number and effector function of CD8⁺ T cells in the LLC and CMT167 tumors (Fig. 9, J–M). No significant loss of body weight, impairment of cardiac function, liver function, renal function, and hematopoiesis were observed in the mice bearing-CMT167 tumors treated with Mel for 2 weeks. Anti-PD-1 monotherapy tended to cause impairments of cardiac functions, as characterized by the increases in plasma aspartate aminotransferase and creatine kinase-MB levels, though the difference was not significant. The combination of Mel with anti-PD-1 treatment did not result in any extra toxicity compared with the anti-PD-1 monotherapy (Table 1). These results indicate that dual COX-2 and EGFR inhibition by Mel improves anti-PD-1 immunotherapy for the LLC and CMT167 tumors with few side effects.

Discussion

Two novel observations have been made in the present study. First, we presented direct evidence that dual COX-2 and EGFR inhibition by a novel flavonoid Mel overcomes resistance to anti-PD-1 immunotherapy in LLC tumors, and improves efficacy of anti-PD-1 immunotherapy in CMT167 tumors. As far as we know, ours was the first investigation that directly illustrates the antitumor immunity effect of Mel. Second, we demonstrated that Mel normalizes tumor vasculature and ameliorates PD-L1-mediated immunosuppression that occurs via COX-2 and EGFR-PI3K/Akt signaling. These findings suggest the vital roles of dual inhibition of COX-2 and EGFR in host antitumor immunity, which could develop into a novel multitarget agency to improve checkpoint blockade therapy for human lung cancer.

Flavonoids are polyphenolic compounds that exert potent antitumor activities with low toxicity (Yang et al., 2015). A previous study in our group showed that flavonoid CH625 increased survival and decreased tumor burden with enhanced antitumor immunity in C6 and GL261 gliomas (Wang et al., 2018). In addition, a recent study from another group has shown that flavone apigenin inhibits PD-L1 expression and enhances T-cell proliferation in breast cancer (Coombs et al., 2016). Here we demonstrated that flavonoid Mel improves anti-PD-1 therapy in the LLC and CMT167 models with few side effects. There are reports of clinically significant side effects in patients receiving nivolumab or pembrolizumab (anti-PD-1 antibody) treatment, including cases of hepatomegaly, interstitial nephritis, as well as pericarditis (Naidoo et al., 2015; Asnani, 2018). Previous studies showed that flavonoids extenuate radiotherapy and chemotherapy-induced toxicities in lung cancer

Fig. 8. PI3K/Akt signal contributes to melafolone-mediated downregulation of VEGF, TGF- β , and PD-L1. (A) A549 cells were treated with Mel (10 and 20 μ M) or vehicle for 24 hours. EP4, p-AKT, and AKT were determined by Western blot. (B) Parental and COX-2^{high} A549 cells were treated with Mel (10 and 20 μ M) or vehicle for 24 hours, followed by treatment with or without PGE₂ (1 μ M) or EGF (20 ng/ml) for another 24 hours. p-AKT and AKT were determined by Western blot. (C) The effects of Akt overexpression on Akt protein levels in A549 cells were measured by Western blot. (D) Parental and Akt^{high} A549 cells treated with Mel (20 μ M) or vehicle for 24 hours. VEGF and TGF- β in the supernatants were determined by ELISA. (E) PD-L1 in the A549 cells treated as described in Fig. 8D was measured by quantitative PCR. (F and G) The condition medium from the A549 cells treated as described in Fig. 8D was added to the lower chamber. Pericyte cells (human brain vascular pericytes, HBVP) or endothelial cells (human umbilical vein endothelial cells, HUVEC) were added to the upper chamber and then incubated overnight. The cells that migrated to the lower chamber were counted. (H) HUVEC were plated at 1×10^4 per well in 96-well culture plates, and then treated with CM described in Fig. 8F. Cell proliferation was measured using MTS assays. (I) The CD8⁺ T cells were stimulated with 2 μ g/ml plate-bound anti-CD3 and anti-CD28 antibodies for 24 hours, and then cocultured with the A549 cells treated as described in Fig. 8D for the indicated time. The proliferation of CD8⁺ T cells was measured by carboxyfluorescein succinimidyl ester dilution. (J) Production of GzmB, IFN- γ , and IL-2 in CD8⁺ T cells was determined by ELISA. Each value represents the mean $\pm$ S.E.M. of five independent triplicate experiments. * P < 0.05; ** P < 0.01 vs. control, # P < 0.05; ## P < 0.01 vs. Mel (20 μ M)-treated group.

(Yin et al., 2012; Hillman et al., 2013). Therefore, further studies are being carried out to test whether flavonoid Mel could ameliorate the anti-PD-1-induced toxicities in lung cancer.

COX-2 expression positively correlates with PD-L1 expression in human lung adenocarcinoma (Shimizu et al., 2017). However, COX-2 inhibitor celecoxib did not decrease PD-L1 expression in NSCLC cells (Shimizu et al., 2018), suggesting another pathway that compensates for the effects of COX-2 inhibition. Here we demonstrated that dual COX-2 and EGFR inhibition by Mel downregulated PD-L1 in lung cancer cells in vivo and in vitro. Conversely, these effects were attenuated by exogenous addition of EGF. Previous studies have shown that EGFR is overexpressed in NSCLC and upregulates PD-L1 expression (Gately et al., 2014; Miura and Sunaga, 2018). Increasing evidence indicates a tight connection between the COX-2 and EGFR pathways in lung cancer (Shi et al., 2017). These results suggest that a highly activated EGFR pathway might compensate for the effects of COX-2

blockade on PD-L1. PD-L1-mediated suppression of activated CD8⁺ T cells is crucial for tumor escape from immune attack on cancer progression (Wang et al., 2016). Here we demonstrated that dual COX-2 and EGFR inhibition by Mel increases the proliferation and effector function of CD8⁺ T cells through PD-L1 downregulation. These results suggest that the dual COX-2 and EGFR inhibition by Mel ameliorates PD-L1-mediated immunosuppression and could be a novel strategy for cancer immunotherapy.

"Vascular normalization" reconditions the tumor immune microenvironment and enhances immunotherapy including antitumor vaccination or adoptive T-cell therapy (Shrimali et al., 2010; Johansson et al., 2012). Here we demonstrated that dual COX-2 and EGFR inhibition by Mel in lung cancer cells normalized tumor vasculature and was accompanied by an increased number of tumor-infiltrated CD8⁺ T cells, thereby facilitating anti-PD-1 treatment in mice bearing LLC or CMT167 tumors. Moreover, dual COX-2 and EGFR inhibition by Mel promoted vascular normalization through

Fig. 9. COX-2 and EGFR inhibition by melafolone improves anti-PD-1 therapy in the Lewis lung carcinoma and CMT167 models. (A) LLC (2×10^5) were injected subcutaneously into the right flank of C57BL/6 mice. When tumors had reached a size of about 100 mm^3 , the mice were treated with anti-PD-1 antibody ($200 \mu\text{g}/\text{mouse}$ every 3 days, i.p.), Mel ($20 \text{ mg}/\text{kg}$ daily, i.p.), anti-PD-1 antibody plus Mel, or vehicle for 7 days. The tumor weight of mice was measured. (B) The survival time of mice was measured. (C) CMT167 (2×10^5) were injected subcutaneously into the right flank of C57BL/6 mice. When tumors had reached a size of about 100 mm^3 , the mice were treated with anti-PD-1 antibody ($200 \mu\text{g}/\text{mouse}$ every 3 days, i.p.), Mel ($20 \text{ mg}/\text{kg}$ daily, i.p.), anti-PD-1 antibody plus melafolone, or vehicle for 14 days. The tumor weight of mice was measured. (D) The survival time of mice was measured. (E) PGE₂ in the tumor cells from the LLC and CMT167 tumors was determined by ELISA. TABLE 1
Effect of melafolone and anti-PD-1 therapy on body weight profile, biochemical profile and complete blood counts in the CMT167 tumor model
The CMT167 cells (2×10^5) were injected subcutaneously into the right flank of C57BL/6 mice. Seven days later when tumors had reached a size of about 100 mm³, the mice were treated with anti-PD-1 (200 μg/mouse every 3 days, i.p.), Mel (20 mg/kg daily, i.p.), anti-PD-1 antibody (200 μg/mouse every 3 days, i.p.) plus Mel (20 mg/kg daily, i.p.), or vehicle for 14 days. The plasma aspartate aminotransferase (AST), alanine aminotransferase (ALT), blood urea nitrogen (BUN), creatine levels, creatine kinase-MB (CK-MB), and complete blood counts, including white blood corpuscles (WBC), red blood corpuscles (RBC), hematocrit (HCT), mean cell volume (MCV), and platelet (PLT) levels, were determined. Data are presented as mean ± S.E.M., n = 8.

Groups	Control	Anti-PD-1	Mel	Mel+ Anti-PD-1
Body weight (g)	26.3 ± 0.6	26.6 ± 0.6	26.6 ± 0.5	27.1 ± 0.7

VEGF or TGF-β downregulation in lung cancer cells. We previously reported that the downregulated TGF-β and VEGF in endothelial progenitor cells (EPCs) and TAMs contributes to glial vascular normalization (Wang et al., 2017a). Therefore, we conclude that COX-2 and EGFR inhibition by Mel normalizes tumor vasculature through VEGF or TGF-β downregulation in cells other than tumor cells in a tumor microenvironment. Further research is being conducted to explore the possibilities.

PI3K/Akt is a crucial signal in tumor angiogenesis (Chen et al., 2017b). We previously reported that the downregulation of PI3K/Akt in TAMs and EPCs promotes glial vascular normalization (Wang et al., 2017a). Here we found that dual COX-2 and EGFR inhibition by Mel reduced proliferation and migration of endothelial cells and enhanced migration of pericyte cells through PI3K/Akt downregulation. PI3K/Akt activation upregulates PD-L1 expression in human lung cancer cells (Zhang et al., 2017), and inhibition of PI3K/Akt signaling exerts antitumor immunity (O'Donnell et al., 2018). In this study, we demonstrated that dual COX-2 and EGFR inhibition by Mel decreased PD-L1 expression in lung cancer cells and increased effector function of CD8⁺ T cells, whereas Akt overexpression attenuated these effects. These data indicate that dual COX-2 and EGFR blockade by Mel induces vascular normalization and ameliorates PD-L1-mediated immunosuppression via PI3K/Akt pathway.

In summary, dual inhibition of COX-2 and EGFR by flavonoid Mel improves anti-PD-1 therapy through vascular normalization and PD-L1 downregulation via the PI3K/Akt pathway. We identify flavonoid Mel as the dual inhibitor of COX-2 and EGFR, by which Mel improves anti-PD-1 therapy with few side effects. Our results may lay a solid foundation for the development of Mel as a novel candidate agent against resistance to checkpoint blockade therapy for human lung cancer.
