ABSTRACT

Valproic acid (VPA) has been shown to regulate the levels of brain-derived neurotrophic factor (BDNF), but it is not known whether this drug can affect the neuronal responses to BDNF. In the present study, we show that in retinoic acid-differentiated SH-SYSY human neuroblastoma cells, prolonged exposure to VPA reduces the expression of the BDNF receptor TrkB at the protein and mRNA levels and inhibits the intracellular signaling, neurotrophic activity, and prosurvival function of BDNF. VPA downregulates TrkB and curtails BDNF-induced signaling also in differentiated Kelly and LAN-1 neuroblastoma cells and primary mouse cortical neurons. The VPA effect is mimicked by several histone deacetylase (HDAC) inhibitors, including the class I HDAC inhibitors entinostat and romidepsin. Conversely, the class II HDAC inhibitor MC1568, the HDAC6 inhibitor tubacin, the HDAC8 inhibitor PCI-34051, and the VPA derivative valpromide have no effect. In neuroblastoma cells and primary neurons both VPA and entinostat increase the cellular levels of the transcription factor RUNX3, which negatively regulates TrkB gene expression. Treatment with RUNX3 siRNA attenuates VPA-induced RUNX3 elevation and TrkB downregulation. VPA, entinostat, HDAC1 depletion by siRNA, and 3-deazaneplanocin A (DZNep), an inhibitor of the polycomb repressor complex 2 (PRC2), decrease the PRC2 core component EZH2, a RUNX3 suppressor. Like VPA, HDAC1 depletion and DZNep increase RUNX3 and decrease TrkB expression. These results indicate that VPA downregulates TrkB through epigenetic mechanisms involving the EZH2/RUNX3 axis and provide evidence that this effect implicates relevant consequences with regard to BDNF efficacy in stimulating intracellular signaling and functional responses.

SIGNIFICANCE STATEMENT

The tropomyosin-related kinase receptor B (TrkB) mediates the stimulatory effects of brain-derived neurotrophic factor (BDNF) on neuronal growth, differentiation, and survival and is highly expressed in aggressive neuroblastoma and other tumors. Here we show that exposure to valproic acid (VPA) downregulates TrkB expression and functional activity in retinoic acid-differentiated human neuroblastoma cell lines and primary mouse cortical neurons. The effects of VPA are mimicked by other histone deacetylase (HDAC) inhibitors and HDAC1 knockdown and appear to be mediated by an epigenetic mechanism involving the upregulation of RUNX3, a suppressor of TrkB gene expression. TrkB downregulation may have relevance for the use of VPA as a potential therapeutic agent in neuroblastoma and other pathologies characterized by an excessive BDNF/TrkB signaling.

Introduction

The short-chain branched fatty acid valproic acid (VPA) is commonly used in the clinic as an anticonvulsant for the treatment of various forms of epilepsy, as a mood stabilizer for the management of bipolar mood disorder, and as an analgesic for migraine headaches (Loscher, 2002). Moreover, in clinical trials VPA has been investigated as a potential anticancer agent for both hematologic and solid tumors (Chateauvieux et al., 2010). This wide array of pharmacological properties likely stems from the ability of VPA to display multiple mechanisms of action, including inhibition of voltage-gated sodium and calcium channels, potentiation of GABAergic transmission, attenuation of glutamatergic function, and alteration of the activity of distinct intracellular signaling mediators (Loscher, 2002). Moreover, VPA at clinically relevant concentrations has been demonstrated to act as an effective inhibitor of histone deacetylases (HDACs) (Gottlicher et al., 2001; Phiel et al., 2001), which play a critical role in the epigenetic regulation of gene transcription (Thiagalingam et al., 2003; Bolden et al., 2006). Among the four distinct classes of mammalian HDACs so far identified, VPA preferentially inhibits HDACs belonging to class I and IIa (Bolden et al., 2006). A number of preclinical studies have shown that VPA can exert neuroprotective effects against a variety of brain insults, suggesting a therapeutic potential in different neurodegenerative conditions.

ABBREVIATIONS: Akt, protein kinase B; BDNF, brain-derived neurotrophic factor; DZNep, 3-deazaneplanocin A; ERK1/2, extracellular signal-regulated kinases 1 and 2; EZH2, enhancer of zeste homolog 2; FCS, fetal calf serum; GAPDH, glyceraldehyde 3-phosphate dehydrogenase; GSK-3β, glycogen synthase kinase-3β; HDAC, histone deacetylase; MAP2, microtubule-associated protein 2; PARP, poly (ADP-ribose) polymerase; PI3K, phosphatidylinositol 3-kinase; PLC, phospholipase C; PMSF, phenylmethylsulphonyl fluoride; PRC2, polycomb repressive complex 2; qPCR, quantitative polymerase chain reaction; RA, all-trans retinoic acid; siRNA, small interfering RNA; TrkB-FN, TrkB full length isoform; TrkB-T, TrkB truncated isoforms; VPA, valproic acid.
Inhibition of TrkB Expression by Valproic Acid

3-Deazaneplanocin A hydrochloride (DZNep), romidepsin (depsipeptide), PCI-345051 (1-(4-methoxybenzyl)-N-hydroxy-1H-indole-6-carboxamide), and tubacin (N1-[4-[(2R)-4,6S]-4-[(4,5-diphenyl-2-oxazolyl)thio][methyl]-6-[(hydroxymethyl)phenyl]-1,3-dioxan-2-yl]phenyl-N8-hydroxy-octanamide) were from MedChem Express Europe (Sollentuna, Sweden). VPA, trichostatin A, sodium butyrate, and 4,6-diamidino-2-phenylindole dihydrochloride (DAPI) were from Sigma-Aldrich (St. Louis, MO).

**Cell Culture.** Human neuroblastoma cell lines SH-SY5Y and LAN-1 were obtained from the European Cell Culture Collection (Salisbury, UK) and grown in Ham’s F12/MEM medium (1:1) supplemented with 2 mM l-glutamine, 1% nonessential amino acids, 10% fetal calf serum (FCS), and 100 U/ml penicillin-100 µg/ml streptomycin (Invitrogen, Carlsbad, CA). The Kelly cell line was obtained from Cell Lines Services GmbH (Eppelheim, Germany) and grown in RPMI 1640 medium supplemented with 2 mM l-glutamine and 10% FCS and 100 U/ml penicillin-100 µg/ml streptomycin. Cells were maintained at 37°C in a humidified atmosphere of 5% CO2 in air.

Cells were differentiated by exposure for 6 to 7 days to all-trans retinoic acid (RA) (Sigma-Aldrich) dissolved in dimethyl sulfoxide. The final RA concentration (10 µM) was obtained by dilution of stock solution in the cell culture medium. The medium was renewed every 48 hours and during the RA treatment care was taken to avoid cell culture exposure to light.

**Primary Cultures of Mouse Cortical Neurons.** CD-1 mice were obtained from Envigo RMS Srl. (S. Pietro al Natisone, Udine, Italy). Primary cultures of cortical neurons were prepared from 1-day-old mice of mixed sexes as previously described (Dedoni et al., 2010). Cells were plated on six-well plates precoated with 0.01% poly-L-lysine (Sigma-Aldrich) at the density of ~1 × 10^5 cells/well and cultured in Neurobasal-A medium (Gibco-Thermo Fisher Scientific, Waltham, MA) supplemented with B-27. Cultures were used 5–7 days after plating and contained ~90% neurons as assessed by immunofluorescence staining with anti-neurofilament 160/200 (NF160/200) and anti-glia fibrillary acidic protein antibodies (Sigma-Aldrich). Experiments were performed according to the recommendations of the European Commission (EU Directive 2010/63/EU for animal experimentation) and were approved by the Institutional Ethical Committee.

**Cell Treatment.** Unless otherwise indicated, RA-treated neuroblastoma cells were washed with PBS and incubated in medium containing 1% FCS. Cultured cortical neurons were washed and kept in Neurobasal-A medium without B-27 supplement. Cells were treated with test agents as indicated at 37°C in a humidified atmosphere of 5% CO2 in air. Control samples received an equal amount of vehicle. Thereafter, cells were washed and scraped into ice-cold lysis buffer containing PBS, 0.1% SDS, 0.5% Nonidet P-40, 0.5% sodium deoxycholate, 2 mM EDTA, 2 mM EGTA, 4 mM sodium pyrophosphate, 2 mM sodium orthovanadate, 10 mM sodium fluoride, 20 mM o-phenylenediamine, 1 mM phenylmethylsulphonyl fluoride (PMSF), 0.5% phosphatase inhibitor cocktail 3, and 1% protease inhibitor cocktail (Sigma-Aldrich) (RIPA buffer). The samples were sonicated for 5 seconds in ice-bath, and aliquots of cell extracts were taken for protein determination by the Bio-Rad protein assay (Bio-Rad Laboratory, Hercules, CA).

**Isolation of Cell Nuclei.** SH-SY5Y cells grown in 100 mm Petri dishes were treated with the agents as indicated, washed with ice-cold PBS (pH 7.4), and scraped in an ice-cold lysis buffer containing PBS, 10 mM Tris-HCl, 2 mM MgCl2, 10 mM NaCl, 0.5 mM EGTA, 2 mM sodium orthovanadate, 10 mM sodium fluoride, 1 mM PMSF, 0.05% Nonidet, 0.5% phosphatase inhibitor cocktail 3, and 1% protease inhibitor cocktail (pH 7.4). Cell lysates were centrifuged at 3000 g for 10 minutes at 4°C, the supernatant was collected and centrifuged at 24,000 g for 20 minutes to obtain a cytosolic fraction. The pellets were washed three times in ice-cold washing buffer containing 10 mM 1,4-piperazinediethanesulfonic acid/KOH, 300 mM sucrose, 2 mM MgCl2, 10 mM NaCl, 0.5 mM EGTA, 2 mM sodium orthovanadate, 10 mM sodium fluoride, 1 mM PMSF, 0.5% phosphatase inhibitor cocktail 3, and 1% protease inhibitor cocktail (pH 7.4). The pellets were sonicated at 3000 g for 10 minutes at 4°C, the supernatant collected and centrifuged at 24,000 g for 20 minutes to obtain a cytosolic fraction. The pellets were washed three times in ice-cold washing buffer containing 10 mM 1,4-piperazinediethanesulfonic acid/KOH, 300 mM sucrose, 2 mM MgCl2, 10 mM NaCl, 0.5 mM EGTA, 2 mM sodium orthovanadate, 10 mM sodium fluoride, 1 mM PMSF, 0.5% phosphatase inhibitor cocktail 3, and 1% protease inhibitor cocktail (pH 7.4) and layered over a cushion of 1 ml of sucrose buffer containing 1 M sucrose, 2 mM sodium...
orthovanadate, 10 mM sodium fluoride, 1 mM PMSF, 0.5% phosphatase inhibitor cocktail 3 and 1% protease inhibitor cocktail. Following centrifugation at 3000 g for 10 minutes at 4°C, the nuclei present in the pellets were washed and the proteins were extracted by incubating the nuclei on ice for 30 minutes in a buffer containing 20 mM 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid/NaOH, 300 mM NaCl, 2 mM MgCl₂, 0.2 mM EDTA, 2 mM sodium orthovanadate, 10 mM sodium fluoride, 1 mM PMSF, 0.5% phosphatase inhibitor cocktail 3 and 1% protease inhibitor cocktail (pH 7.9). Following centrifugation at 24,000 g for 10 minutes at 4°C, the nuclear extracts were mixed with sample buffer and analyzed by Western blot.

Transfection of Small Interfering RNA. SH-SY5Y cells were transfected with either 50 pmol/ml of control small interfering RNA (siRNA)-A (sc-37007; Santa Cruz Biotechnology), HDAC1 siRNA (siRNA-A; sc-29343; Santa Cruz Biotechnology), or RUNX3 siRNA (sc-37679; Santa Cruz Biotechnology) duplexes using Lipofectamine RNAiMAX (Invitrogen) as a transfection reagent. Control siRNA consisted of a nontargeting sequence. Cells grown in six-well plates were incubated in antibiotic-free medium for 24 hours. The medium was renewed and the cells were incubated with siRNA duplexes for 4 to 5 hours at 37°C. Thereafter, the medium was replaced by the growth medium, and the cells were analyzed 48 hours posttransfection. To determine transfection efficiency, parallel samples were transfection with fluorescein-conjugated control siRNA-A (sc-36869; Santa Cruz Biotechnology). An efficiency of 50%–60% was obtained in six separate experiments.

RNA Extraction and Quantitative Polymerase Chain Reaction. SH-SY5Y cells were incubated in a medium containing 1% FCS and treated for 24 hours with either vehicle or 1 mM VPA. Thereafter, the cells were washed with PBS and total RNA was isolated by using TRIzol reagent (Invitrogen) with the PureLink RNA Kit (Invitrogen) as a transfection reagent. After RNA purification on a Turbo DNase (Ambion by Life Technologies) digestion was performed. The purity and quantity of the RNA isolated were determined by measuring UV absorbance at 260 and 280 nm.

First-strand cDNA synthesis was performed using 2 μg of total RNA, following the manufacturer’s protocol (SuperScript VILO cDNA synthesis kit; Invitrogen). Two-hundred nanograms of cDNA for reaction was used for quantitative polymerase chain reaction amplification with SYBR Green PCR Master Mix (Applied Biosystems). The quantitative polymerase chain reaction analysis was carried out on a real-time PCR system (StepOne; Applied Biosystems) under the following conditions: an initial holding stage at 95°C for 10 minutes was followed by 45 cycles: denaturation at 95°C for 15 seconds, primer annealing and extension at 60°C for 1 minute, and a dissociation curve to the end of a real time run (melt curve 95°C for 15 seconds, 60°C for one minute and 95°C for 15 seconds). The PCR primers used were: human TrkB (NCBI accession number NM_006180.2) forward ACAGTCTGACCGAACCGACAC, reverse GTTCTGTCAGGACAGATTTA; human β-actin (NCBI accession number NM_001103.1) forward AGGCTGCGCCCTTTGGCCTC, reverse CATGCGCCAGCCTTGTGCAC. The comparative Ct values method was used to calculate the relative quantity of TrkB expression. For both control and VPA-treated samples, the β-actin Ct values were subtracted from the TrkB Ct values to obtain the ΔCt value. ΔCt values were obtained according to ΔCt (VPA-treated samples) – ΔCt (control samples). The relative quantity was calculated according to 2^(-ΔΔCt).

Biotinylation of Surface Proteins. Surface biotinylation of cell proteins was performed as previously described (Dedoni et al., 2012). Differentiated SH-SY5Y cells were grown in 100 mm plates and treated at confluency with either vehicle or VPA (1 mM) for 24 hours in medium containing 1% FCS. Thereafter the cells were washed three times with ice-cold PBS (pH 8.0) and incubated for 45 minutes at 4°C with the cell impermeable biotinylating agent sulfo-LC-biotin (300 μmol/ml) (Pierce, Rockford, IL). Thereafter, the medium was aspirated and the cells washed three times with ice-cold PBS containing 20 mM glycine. Cells were then solubilized by incubation for 60 minutes at 4°C in RIPA buffer supplemented with 1% Triton × 100. Cell extracts were centrifuged at 14,000 g for 5 minutes at 4°C, and the supernatants were incubated overnight with streptavidin-conjugated agarose beads with continuous rotation at 4°C. The samples were then centrifuged to obtain a supernatant and a pellet fraction containing the plasma membrane-associated proteins. The agarose beads were washed three times with ice-cold Tris buffer containing 10 mM Tris-HCl (pH 7.5), 2.5 mM EDTA, 150 mM NaCl, and 1% Triton × 100, followed by two washes with 10 mM Tris-HCl (pH 7.5), 2.5 mM EDTA, 500 mM NaCl, and 0.1% Triton × 100 and one final wash with 50 mM Tris-HCl (pH 7.5). The pellets were then mixed with sample buffer and incubated 2 minutes at 100°C. The proteins were then analyzed by Western blot.

Western Blot Analysis. Cells were proteins were separated by SDS-polyacrylamide gel and electrophoretically transferred to polyvinylidene difluoride membranes (Amersham Biosciences, Piscataway, NJ). Membranes were blocked, washed, and incubated overnight at 4°C with one of the following primary antibodies: TrkB (cat. no. 4603; Cell Signaling Technology, Danvers, MA) (1:1000), TrkA (cat. no. 2508; Cell Signaling Technology) (1:1000), TrkC (cat. no. 3376; Cell Signaling Technology) (1:1000), phospho-TrkA (Tyr674/675)/TrkB (Tyr706/707) (cat. no. 4621; Cell Signaling Technology) (1:1000), p75NTR (cat. no. 8238; Cell Signaling Technology) (1:1000), synapsin-1 (cat. no. 5297; Cell Signaling Technology) (1:2000), pan-cadherin (cat. no. 4073; Cell Signaling Technology) (1:1000), phospho-S6 ribosomal protein (Ser235/236) (cat. no. 4856; Cell Signaling Technology), S6 ribosomal protein (cat. no. sc-74459; Santa Cruz Biotechnology) (1:1000), phospho-Akt (Thr308) (cat. no. 2965; Cell Signaling Technology) (1:1000), Akt1/2/3 (cat. no. sc-8312; Santa Cruz Biotechnology) (1:1000), phospho-glycogen synthase kinase (GSK)-3β (Ser9) (cat. no. 9356; Cell Signaling Technology) (1:1000), GSK-3β (cat. no. sc-9166; Santa Cruz Biotechnology) (1:2000), extracellular signal-regulated kinases 1 and 2 (ERK1/2) (cat. no. 9102; Cell Signaling Technology) (1:1000), phospho-ERK1/2 (Thr202/Tyr204)/ERK2 (Thr185/Tyr187) (cat. no. RA15002; NeuroMics, Northfield, MN) (1:15,000), phospholipase C-γ (PLC-γ1) (cat. no. 2822; Cell Signaling Technology) (1:1000), phospho-PLC-γ1 (Tyr783) (cat. no. 2821; Cell Signaling Technology) (1:1000), cleaved-poly(ADP-ribose) polymerase (PARP) (Asp214) (cat. no. 5625; Cell Signaling Technology) (1:1000), PARP (cat. no. 9542; Cell Signaling Technology) (1:1000), enhancer of zeste homolog 2 (EZH2) (cat. no. 5246; Cell Signaling Technology) (1:2000), RUNX3/AML2 (cat. no. 9647; Cell Signaling Technology) (1:1000), postsynaptic density 95 (PSD95) (cat. no. 3450; Cell Signaling Technology) (1:2000), GhuR1 (cat. no. 2040; Tocris Cookson Ltd., Avonmouth, UK) (1:1000), HDAC1 (cat. no. sc-81598; Santa Cruz Biotechnology) (1:5000), histone H3 (cat. no. GTX122148; GeneTex Inc., Irvine, CA) (1:2000), histone H3 (acetyl-Lys9/Lys14) (cat. no. GTX122648; GeneTex Inc., TX) (1:1000), MAP2 (cat. no. 188011; Synaptic Systems GmbH, Göttingen, Germany) (1:1000), actin (cat. no. A2066; Sigma-Aldrich) (1:3000), actin (cat. no. A5441; Sigma-Aldrich) (1:20,000), and glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (cat. no. 247002; Synaptic Systems GmbH) (1:1000). Thereafter, the membranes were washed and incubated with an appropriate horseradish peroxidase-conjugated secondary antibody (Santa Cruz Biotechnology). Immunoreactive bands were detected using Clarity Western ECL substrate (Bio-Rad Laboratory.) and ECL Hyperfilm (Amersham). The size of immunoreactive bands was determined by using molecular weight standards detected with an ECL suitable antibody (cat. no. sc-2035; Santa Cruz Biotechnology) (1:1000). Band densities were determined using Image Scanner III (GE Healthcare, Milan, Italy) and NIH ImageJ software (US National Institutes of Health, Bethesda, MA). The optical density of the phosphorylated protein bands was normalized to the density of the corresponding total protein. For analysis of PARP, the formation of thecleaved protein was normalized to the level of the uncleaved PARP determined in the same samples. For the remaining proteins, the densitometric values were normalized to the levels of either actin, GAPDH, or subcellular fraction marker, as indicated.

Immunoﬂuorescence Analysis. Differentiated SH-SY5Y cells grown on poly-l-lysine-coated coverslips were treated with the test agents as indicated in the text, washed, and fixed in 4% paraformaldehyde for
30 minutes at room temperature. For analysis of TrkB, nonpermeabilized cells were blocked with 3% BSA and 1% normal goat serum and incubated overnight with an antibody directed against an extracellular domain of TrkB (1:500) (cat. no. ANT-019; Alomone Laboratories). For analysis of neuritogenesis and detection of cleaved-caspase 3, cells were permeabilized with 0.2% Triton X-100, blocked, and incubated overnight at 4°C with mouse anti-actin (cat. no. A5441; Sigma-Aldrich) (1:5000) and rabbit anti-cleaved caspase-3 (cat. no. 9661; Cell Signaling Technology) (1:200), respectively.

Cells were then incubated with an appropriate Alexa-Fluor488- or Alexa-Fluor594-conjugated secondary antibody (Invitrogen-Molecular Probes), and cell nuclei were stained with 0.1 μg/ml 4',6-diamidino-2-phenylindole. Cells were analyzed with an Olympus BX61 microscope equipped with a F-View II CCD-camera by using either a ×40 or a ×60 objective lens. Digital images were acquired using constant camera settings within each experiment and were analyzed using the program Cell P (Olympus Soft Imaging Solutions, Homburg, Germany). At least 15 fields were randomly selected for each sample, and only cells showing an unobstructed nucleus or soma were considered.

For quantification of neuritogenesis, at least 10 fields were analyzed for each sample run in triplicate and in each field the cell bodies and neurites were counted. Processes with length equal to two or more cell body diameters were scored as neurites. The ratio of neurites to cell bodies was calculated and expressed as mean ± S.E.M. Four separate preparations of SH-SY5Y cells were examined. For analysis of TrkB and cleaved caspase 3 expression, the average pixel intensity was measured within the region of the cell soma or the nucleus and in an adjacent area, which was used as background value. Cells were deemed to be positive if the average pixel intensity was equal or above a threshold value corresponding to 1 S.D. above the average pixel intensity of the respective control samples (Dedoni et al., 2017). No labeling was detected in samples treated without background value. Cells were deemed to be positive if the average pixel intensity was equal or above a threshold value corresponding to 1 S.D. above the average pixel intensity of the respective control samples (Dedoni et al., 2017). No labeling was detected in samples treated without background value.

Cell P (Olympus Soft Imaging Solutions, Homburg, Germany). At least 15 fields were randomly selected for each sample, and only cells showing an unobstructed nucleus or soma were considered.

Fig. 1. VPA downregulates TrkB expression in RA-differentiated neuroblastoma cells. (A) SH-SY5Y cells were treated as in (A), and the expression of TrkA (C), TrkC (D), and p75NTR (E) was determined in cell lysates. (F and G) Kelly (F) and LAN-1 (G) cells were treated for 24 hours with either vehicle or 1 mM VPA. Values are the mean ± S.E.M. of four independent determinations. (C–E) SH-SY5Y cells were treated as in (A), and the expression of TrkA (C), TrkC (D), and p75NTR (E) was determined in cell lysates. (F and G) Kelly (F) and LAN-1 (G) cells were treated for 24 hours with either vehicle or VPA (1 mM). Cell lysates were then analyzed for TrkB expression. Values are the mean ± S.E.M. of four (Kelly) and seven (LAN-1) experiments. *P < 0.05; **P < 0.01 vs. control (vehicle) by Student’s t test.

Results

VPA Downregulates TrkB Expression in RA-Differentiated Neuroblastoma Cells. In agreement with previous studies (Kaplan et al., 1993; Encinas et al., 1999; Dedoni et al., 2012), Western blot analysis of TrkB expression in RA-differentiated SH-SY5Y cells detected the presence of an immunoreactive band of 145 kDa representing the catalytic tyrosine kinase full-length isoform of TrkB (TrkB-FL) and an additional broader band of ~95 kDa, which corresponded to the molecular mass of the truncated TrkB (TrkB-T) isoforms TrkB.T1 and TrkB.Tc lacking the tyrosine kinase domain (Fig. 1A) (Klein et al., 1990; Stoilov et al., 2002). Prolonged (24 hours) cell treatment with VPA (1 mM) reduced the expression levels of the 145- and 95-kDa isoforms by 63% ± 6% and 47% ± 5% (P < 0.001, N = 6), respectively (Fig. 1A). Quantitative RT-PCR analysis indicated that VPA reduced the level of TrkB mRNA by 45% ± 5% (P < 0.001, N = 3) (Fig. 1B).

We also investigated the effects of VPA on other neurotrophin receptors whose expression is known to be enhanced by RA treatment of neuroblastoma cells. Prolonged exposure using the program Graph Pad Prism 5 (San Diego, CA). Unless otherwise indicated, data are expressed as percentage or fold stimulation of control, which was included in each independent experiment. The control group was set as 100 or 1, with a variance obtained by expressing each control value as a percentage of the mean of the raw values of the control group. In the experiments in which control values were equal to zero, values of experimental groups were expressed as a percentage of the maximal effect set as 100. The variance of this value was determined in the same manner as for the control group. Statistical analysis was performed by either Student’s unpaired t test or one-way analysis of variance followed by Newman-Keuls post hoc test as appropriate. A value of P < 0.05 was considered to be statistically significant.

Statistical Analysis. Results are reported as the mean ± S.E.M. of N independent experiments. Statistical analysis was performed by
of differentiated SH-SY5Y cells to VPA (1 mM) failed to significantly affect the protein levels of TrkA, the receptor of nerve growth factor (Fig. 1C), but markedly enhanced the expression of the full-length and truncated isoforms of TrkC, the receptor for neurotrophin 3 (Fig. 1D), and the common neurotrophin receptor p75NTR (Fig. 1E). Densitometric values of vehicle- and VPA-treated samples (expressed as fold changes with respect to vehicle set to 1.0) were: TrkA 1.28 ± 0.05 (P > 0.05, N = 4); TrkC-FL 20 ± 3, TrkC-T 6.5 ± 1.0 (P < 0.001, N = 3); p75NTR 50 ± 8 (P < 0.001, N = 6).

We examined the effects of VPA on TrkB expression in two additional human neuroblastoma cell lines, LAN-1 and Kelly, which, differently from SH-SY5Y cells, display MYCN oncogene amplification. Both Kelly and LAN-1 cells predominantly expressed the TrkB-FL isoform upon RA exposure (Supplemental Fig. 1). Treatment with VPA (1 mM) for 24 hours decreased the levels of TrkB-FL by 46% ± 5% (P < 0.001, N = 4) and 32% ± 4% (P < 0.05, N = 7) in Kelly and LAN-1 cells, respectively (Fig. 1, F and G).

The VPA inhibition of TrkB expression was time dependent, being significant after 6 hours of treatment and increasing progressively up to 24 hours (Fig. 2A). The inhibitory effect was also concentration dependent, being absent at 0.1 and 0.3 mM VPA and increasing as the drug concentrations were elevated from 0.6 to 3 mM (Fig. 2B).

To investigate whether VPA affected the plasma membrane expression of TrkB, surface protein biotinylation experiments were performed in SH-SY5Y cells. As shown in Fig. 3A, exposure to VPA (1 mM) reduced the cell surface levels of TrkB-FL and TrkB-T by 65% ± 6% and 47% ± 5% (P < 0.001, N = 4), respectively, compared with vehicle-treated cells. Moreover, immunofluorescence analysis of TrkB in nonpermeabilized cells, using an antibody directed against an extracellular domain of the receptor to detect its plasma membrane expression, indicated that VPA treatment decreased the percentage of TrkB-positive cells by 64% ± 4% (P < 0.001, N = 4) (Fig. 3B).

VPA Exposure Inhibits BDNF-Induced TrkB Activation and Signaling. BDNF-induced TrkB activation involves the receptor autophosphorylation at distinct tyrosine residues located in the intracytoplasmatic domain, which regulates the receptor activity and allows the docking of adaptor signaling molecules. Exposure of SH-SY5Y cells to VPA (1 mM) induced a marked inhibition of BDNF (1 nM)-induced TrkB phosphorylation at Tyr706/707, which occurs within the activation loop of the catalytic domain and enhances the integral receptor tyrosine kinase activity (Huang and Reichardt, 2003) (Fig. 4A).

The inhibitory effect of VPA remained significant when phospho-TrkB levels were normalized to those of total TrkB-FL, indicating that VPA-induced TrkB-FL downregulation was associated with impairment of BDNF-induced receptor activation.

VPA treatment markedly reduced the ability of BDNF to trigger the activation of PLCγ and PI3K/Akt signaling pathways, which are predominantly involved in the promotion of synaptic plasticity.
plasticity and neuronal survival, respectively (Huang and Reichardt, 2003). In SH-SY5Y, cells pre-exposed to VPA (1 mM) the phosphorylation of PLCγ1 at Tyr783, which is essential for neurotrophin-induced PLCγ1 activation (Kim et al., 1991), was reduced by 67% ± 7% (P < 0.001, N = 4) (Fig. 4B). VPA inhibited the BDNF-induced phosphorylation of Akt at Thr308 by 46% ± 4% (P < 0.001, N = 4) (Fig. 4C) and phosphorylation of the Akt substrate GSK-3β at Ser9 by 40% ± 5% (P < 0.001, N = 4) (Fig. 4D).

Activation of ERK1/2 constitutes another major signaling pathway activated by the BDNF-TrkB receptor complex. As shown in Fig. 4, E and F, in SH-SY5Y cells, BDNF (0.05 and 0.1 nM) stimulated the phosphorylation of ERK1/2 and the downstream ERK1/2 target S6 ribosomal protein in a concentration dependent manner, and these responses were markedly reduced in cells pre-exposed to VPA.

Significant inhibitory effects of VPA (1 mM) on BDNF-induced phosphorylation of Akt and GSK-3β were also observed in LAN-1 and Kelly cells (Fig. 4, G and H).

**VPA Reduces the Proneurotrophic and Antiapoptotic Activities of BDNF.** The induction of TrkB following treatment with RA allows neuroblastoma cells to respond to BDNF with neuronal differentiation, as indicated by the appearance of morphologic changes and the enhanced expression of neuronal
markers (Kaplan et al., 1993; Encinas et al., 1999; Dedoni et al., 2012). SH-SY5Y cells treated with RA mostly showed large cell bodies with a polygonal shape and short neurites (Fig. 5A), whereas the exposure of the cells to BDNF (1 nM) for 48 hours increased the percentage of cells with a smaller and rounded cell body and long neuritic processes. Cells treated with VPA (1 mM) for 72 hours displayed a morphology similar to that of vehicle-treated cells. However, when the cells were preincubated for 24 hours with VPA and then exposed to BDNF and VPA for 48 hours, there was a significant reduction in the percentage of neurite-bearing cells compared with cells treated with the neurotrophin alone (Fig. 5A).

Fig. 5. VPA curtails BDNF-induced proneurotrophic and antiapoptotic responses. (A) SH-SY5Y cells were preincubated for 24 hours with either vehicle or 1 mM VPA and then exposed for 48 hours to either vehicle or 1.0 nM BDNF. Cells were fixed and stained with an antiactin antibody (red color). Nuclei were stained in blue with DAPI. For each sample, the number of neurite-bearing cells was determined and calculated as percent of total cells. Values are the mean ± S.E.M. of three separate experiments. (B–E) Cells were preincubated for 24 hours with either vehicle, VPA 0.6 mM (VPA 0.6), or VPA 1.0 mM (VPA 1.0) and then exposed to either vehicle or 1 nM BDNF for 48 hours. Cell lysates were analyzed for the expression of MAP2 (B), synapsyn-1 (synap-1) (C), GluR1 (D), and postsynaptic density 95 (PSD95) (E). Values are the mean ± S.E.M. of four experiments. (F) SH-SY5Y cells were pretreated for 24 hours with either vehicle or 1 mM VPA and then incubated in serum-free medium in the absence and in the presence of 1 nM BDNF for 48 hours. Cells were fixed and analyzed by immunofluorescence for cleaved caspase 3 expression (green color). Cell nuclei were stained with DAPI. For each sample, the number of cleaved caspase 3-positive cells was determined and calculated as percent of total cells. Values are the mean ± S.E.M. of three experiments. (G) SH-SY5Y cells were treated as indicated in (F) and cell lysates were analyzed for cleaved PARP (cleav PARP) and uncleaved PARP (PARP). Values are the mean ± S.E.M. of three experiments. *P < 0.05; ***P < 0.001 vs. control (vehicle); #P < 0.05; ###P < 0.001 vs. BDNF alone by ANOVA followed by Newman-Keuls post hoc test.
The microtubule-associated protein 2 (MAP2) is a major component of the neuronal cytoskeleton and comprises proteins with high molecular mass (MAP2A and MAP2B, ~270 kDa) and low molecular mass (MAP2C, ~70 kDa) (Garnier and Matus, 1988). Western blot analysis of MAP2 expression in RA-differentiated SH-SY5Y cells with an antibody that recognizes all three MAP2 forms detected a single immunoreactive band of ~70 kDa, indicating the presence of MAP2C. Prolonged exposure to BDNF increased the expression of MAP2 by about threefold, and this effect was prevented by cell pretreatment with 0.6 and 1 mM VPA (Fig. 5B). Cell treatment with BDNF also enhanced the steady-state levels of synapsin-1 proteins (Fig. 5C), which regulate synaptogenesis and neurotransmitter release (Cesca et al., 2010), the glutamate AMPA receptor subunit GluR1 (Fig. 5D), and the scaffolding protein postsynaptic density 95 (Fig. 5E). Cell pretreatment with VPA (0.6 and 1 mM) significantly curtailed these neurotrophic responses to BDNF.

Prolonged serum withdrawal induces apoptotic cell death of SH-SY5Y cells (Macleod et al., 2001; Dedoni et al., 2017). Addition of BDNF (1 nM) to the serum-free medium protected against apoptosis, as indicated by the significant decrease in the percentage of cleaved caspase 3-positive cells (Fig. 5F). In cells pretreated with VPA (1 mM), the prosurvival effect of BDNF was almost completely abrogated. In serum-starved cells BDNF also significantly reduced the levels of PARP cleaved at Asp 186, almost completely abrogated. In serum-starved cells BDNF also significantly reduced the levels of PARP cleaved at Asp 186, and this effect was prevented by pre-exposure to VPA (Fig. 5G).

**HDAC Inhibitors and HDAC1 Knockdown Mimic the Inhibitory Effect of VPA on TrkB Expression and Signaling.** We investigated whether epigenetic mechanisms were involved in the downregulation of TrkB induced by VPA. To this goal, we first examined whether other HDAC inhibitors could mimic the effect of VPA. As shown in Supplemental Fig. 2, A–D, incubation of RA-differentiated SH-SY5Y cells with either VPA (1 mM); trichostatin A (300 nM), a broad spectrum HDAC inhibitor (Bolden et al., 2006); the class I inhibitor entinostat (1 μM) (Saito et al., 1999; Hu et al., 2003); or MC 1568 (10 μM), a class II HDAC inhibitor (Mai et al., 2005), elicited a time-dependent increase in the acetylation of histone H3 at Lys9/Lys14, which became evident 1–3 hours after drug exposure. Prolonged cell treatment with either romidepsin (40 nM), a selective inhibitor of the class I members HDAC1 and 2, or the short-chain fatty acid sodium butyrate (1 mM), which shares with VPA the ability to preferentially block class I and IIa HDAC (Bolden et al., 2006), markedly increased H3 acetylation (Supplemental Fig. 2E). Both HDAC6 and HDAC8 have been found to be expressed in human neuroblastoma cells, and their specific inhibition by tubacin and PCI-34051, respectively, has been shown to inhibit the growth and viability of these cells (Subramanian et al., 2011; Rettig et al., 2015). Consistent with previous studies (Haggarty et al., 2003; Balasubramanian et al., 2008), we found that both tubacin and PCI-34051, used at concentrations low enough to maintain their HDAC selectivity, failed to induce H3 histone acetylation (Supplemental Fig. 2E). A lack of effect was also observed in cells treated with the carboxamide derivative of VPA valpromide (1 mM) (Supplemental Fig. 2E), which lacks HDAC inhibitory activity (Phiel et al., 2001).

As observed with VPA, prolonged exposure (24 hours) of differentiated SH-SY5Y cells to either sodium butyrate (1 mM), trichostatin A (300 nM), entinostat (1 μM), or romidepsin (40 nM) elicited a significant decrease in the expression of both TrkB-FL and TrkB-T isoforms (Fig. 6, A–C). Immunofluorescence assays indicated that entinostat (1 μM) decreased the percentage of TrkB-positive cells by 80% ± 4% (P < 0.001, N = 4) (Fig. 6D). Conversely, cell treatment with either MC1568 (10 μM) (Fig. 6A), PCI-34051 (4 μM), tubacin (5 μM), or valpromide (1 mM) failed to affect TrkB expression (Fig. 6, E and F). Like VPA, trichostatin A and sodium butyrate induced a significant inhibition of BDNF-induced Akt phosphorylation, whereas valpromide and MC 1568 were without effect (Fig. 6, G and H). Entinostat (0.5 and 1 μM) caused a concentration-dependent inhibition of BDNF-stimulated phosphorylation of Akt and ERK1/2 (Fig. 6I). Similarly, cell treatment with romidepsin (20 and 40 nM) induced a significant decrease of BDNF-induced phosphorylation of Akt and GSK-3β (Fig. 6J).

We next examined the effects of knocking down HDAC1, an HDAC isoform that regulates neuronal survival and death (Bardai et al., 2012) and is inhibited by therapeutically relevant concentrations of VPA (Phiel et al., 2001). As shown in Fig. 6K, treatment of differentiated SH-SY5Y cells with siRNA targeting HDAC1 decreased HDAC1 protein levels by 60% ± 12% (P < 0.05, N = 3) and increased the level of acetylated histone H3 by 70% ± 10% (P < 0.001, N = 3) compared with control siRNA-treated cells. In HDAC1-depleted cells there was a significant decrease in the expression of both TrkB-FL and TrkB-T (Fig. 6L). VPA Uregulates RUNX3 Expression. To investigate the involvement of transcriptional mechanisms in VPA-induced downregulation of TrkB, we examined the effects of VPA on the transcription factor RUNX3, a suppressor of TrkB expression (Kramer et al., 2006; Inoue et al., 2007). As shown in Fig. 7, A and B, exposure of differentiated SH-SY5Y cells to VPA induced a time- and concentration-dependent increase in RUNX3 protein levels. These effects occurred within the same concentration range of VPA required to increase histone H3 acetylation (Fig. 7B) and were mirrored by similar changes in the steady-state nuclear content of the transcription factor (Fig. 7C). An increase of RUNX3 levels was also observed in Kelly and LAN-1 cells following exposure to either VPA (1 mM) or entinostat (1 μM) (Supplemental Fig. 3, A and B).

**Involvement of RUNX3 in VPA-Induced TrkB Downregulation.** To investigate whether the enhanced expression of RUNX3 participates in TrkB downregulation by VPA, differentiated SH-SY5Y cells were transfected with siRNA duplexes targeting RUNX3. This treatment attenuated the increase in RUNX3 protein levels elicited by VPA and significantly reduced the downregulation of TrkB expression induced by the drug (Fig. 7D).

In human neuroblastoma cells, RUNX3 gene transcription has been reported to be under inhibitory control by the histone methyltransferase EZH2, the catalytic subunit of PRC2 (Wang et al., 2012). Exposure of RA-treated SH-SY5Y cells to VPA (1 mM) reduced EZH2 protein levels by 60% ± 5% (P < 0.001, N = 4) (Fig. 7E). Moreover, in these cells, TrkB downregulation induced by HDAC1 depletion was associated with a decrease of EZH2 and an increase of RUNX3 protein levels (Fig. 7F). A significant decrease of EZH2 was also observed in Kelly and LAN-1 cells following treatment with either VPA (1 mM) or entinostat (1 μM) (Supplemental Fig. 3, C and D).

To further investigate the involvement of the EZH2/RUNX3 axis in the regulation of TrkB expression, we examined the effects of the cyclopentenyl analog of 3-deazaadenosine
Fig. 6. HDAC inhibitors and HDAC1 knockdown mimic the inhibitory effect of VPA on TrkB expression and signaling. (A–C) SH-SY5Y cells were incubated for 24 hours with either vehicle, 1 mM sodium butyrate, 300 nM trichostatin A (TSA), 10 μM MC1568 (A), 1 μM entinostat (B), or 40 nM romidepsin (C). Cell lysates were then analyzed for TrkB expression. Values are the mean ± S.E.M. of four experiments. *P < 0.05; **P < 0.001 vs. the respective control (vehicle) by Student’s t test.

(D) SH-SY5Y cells were incubated for 24 hours with either vehicle or 1 μM entinostat and then TrkB expression was analyzed by immunofluorescence (green color) in nonpermeabilized cells stained with an antibody directed against an extracellular domain of the receptor. Nuclei were stained in blue with DAPI. Images are representative of four independent experiments. Scale bar, 25 μm.

(E and F) SH-SY5Y cells were incubated for 24 hours with either vehicle, 4 μM PCI-34051, 5 μM tubacin (E), or 1 mM valpromide (VPM) (F). Values are the mean ± S.E.M. of four experiments. (G and H) SH-SY5Y cells were preincubated for 24 hours with either vehicle, 300 nM TSA, 1 mM VPM (G), 1 mM sodium butyrate, or 10 μM MC1568 (H) and then exposed for 5 minutes to 1 nM BDNF. Values are the mean ± S.E.M. of three experiments. (I and J) SH-SY5Y cells were preincubated for 24 hours with either vehicle, 0.5 μM entinostat (ent 0.5), 1 μM entinostat (ent 1), 20 nM romidepsin (romi 20), or 40 nM romidepsin (romi 40) (J) and then exposed for 5 minutes to 1 nM BDNF. Values are the mean ± S.E.M. of four experiments. **P < 0.001 vs. control; #P < 0.05; ###P < 0.001 vs. BDNF and vehicle by ANOVA followed by Newman-Keuls post hoc test. (K and L) SH-SY5Y cells were transfected with either control siRNA or HDAC1 siRNA duplexes and cell lysates were analyzed for HDAC1, H3 acetyl-Lys9/Lys14 (Ac-H3), total H3 (K), and TrkB expression (L). Each lane was loaded with a sample of an independent transfection. Values are the mean ± S.E.M. of three experiments. *P < 0.05; **P < 0.001 vs. control siRNA by Student’s t test.
Fig. 7. Involvement of RUNX3 in VPA-induced downregulation of TrkB. (A) SH-SY5Y cells were incubated with 1 mM VPA for the indicated periods of time. Zero time samples were treated with vehicle and used as control. (B) Cells were treated for 24 hours with the indicated concentrations of VPA. Cell lysates were analyzed for the protein levels of RUNX3 and H3-acetyl-Lys9/Lys14 (Ac-H3). Values are the mean ± S.E.M. of four experiments. *P < 0.05; ***P < 0.001 vs. control (vehicle) by ANOVA followed by Newman-Keuls post hoc test. (C) SH-SY5Y cells were incubated with either vehicle or 1 mM VPA for 24 hours. Nuclear extracts were prepared and analyzed for RUNX3 and HDAC1 levels. Values are the mean ± S.E.M. of four experiments. ***P < 0.001 by Student’s t test. (D) SH-SY5Y cells transfected with either control siRNA or RUNX3 siRNA were incubated for 24 hours with either vehicle, 0.6 mM VPA (VPA 0.6), or 1 mM VPA (VPA 1.0). Cell lysates were then analyzed for RUNX3 and TrkB expression. Values are the mean ± S.E.M. of three experiments. ***P < 0.001 vs. control siRNA vehicle; #P < 0.05; ###P < 0.001 vs. the corresponding value in control siRNA-treated group by Student’s t test. (E) SH-SY5Y cells were treated for 24 hours with either vehicle or 1 mM VPA. Cell lysates were analyzed for EZH2 protein levels. Values
VPA Downregulates TrkB Expression and BDNF Signaling in Primary Mouse Cortical Neurons. To assess whether TrkB expression and function was altered by VPA in a nontumoral neuronal cell model, we employed primary cultures of mouse cortical neurons. As shown in Fig. 8A, prolonged exposure (24 hours) of these cultures to either VPA (1 mM) or entinostat (1 μM) produced a significant decrease in the levels of TrkB-FL and TrkB-T. The treatment with VPA and entinostat also induced a reduced receptor autophosphorylation and Akt activation in response to BDNF (1 nM) (Fig. 8, B and C). Moreover, as observed in human neuroblastoma cells, VPA (1 mM) and entinostat (1 μM) significantly increased histone H3 acetylation, decreased EZH2 levels, and increased RUNX3 expression (Fig. 8, D–F).

Discussion

By inhibiting HDAC activity and promoting chromatin remodeling, VPA may affect the expression of a variety of target genes, thus extending its spectrum of action beyond the acute regulation of neurotransmission. The present study shows that in neuronal cells, prolonged in vitro exposure to VPA and other HDAC inhibitors downregulates the expression and functional activity of TrkB, a key mediator of BDNF and neurotrophin 4 actions on neuronal growth, survival, and differentiation.

The downregulation of TrkB occurred at VPA concentrations (0.6–1.0 mM) that are within the plasma concentrations associated with therapeutic effects in epilepsy (40–100 μg/ml, ~0.3–0.7 mM) (Loscher, 2002). In clinical studies investigating the antitumor efficacy of VPA, the median total and free concentrations in plasma were 1.51 and 0.61 mM, respectively (Munster et al., 2009). VPA-induced TrkB downregulation was associated with a marked decrease in the cell surface levels of the receptor. This change is relevant because previous studies have shown that in neurons the majority of TrkB immunoreactivity is located intracellularly, whereas the cell surface receptor population is the one responsive to neurotrophins (Du et al., 2000). It was therefore important to assess whether the downregulation of cell surface TrkB induced by VPA translated into a reduction in intracellular signaling and neurotrophic responses elicited by BDNF. We found that the exposure to VPA inhibited the activation of different components of the intracellular signaling cascade triggered by BDNF via TrkB-FL, such as PLCγ1, Akt, GSK-3β, and ERK1/2. Activation of Akt and the downstream suppression of GSK-3β through phosphorylation at Ser9 are critical events for promoting cell survival (Beurel and Jope, 2006), and their inhibition by VPA correlates with the observed drug-induced impairment of BDNF protection against apoptosis triggered by serum withdrawal. Similarly, the inhibition of ERK1/2 activation may underlie the VPA ability to counteract the changes in neuronal morphology induced by BDNF, as ERK1/2 has been shown to be required for neuronal differentiation and stimulation of neurite outgrowth elicited by the neurotrophin (Encinas et al., 1999; Huang and Reichardt, 2003). Collectively, these results suggest that the VPA-induced downregulation of TrkB-FL implicates relevant consequences with regard to the efficacy of BDNF in stimulating intracellular signaling and functional responses.

TrkB-T isoforms have been proposed to modulate BDNF signaling via TrkB-FL either by sequestering the neurotrophin (Biffi et al., 1995) and/or by acting as dominant negative (Eide et al., 1996). It has also been shown that TrkB-T may regulate the cell surface expression of TrkB-FL (Haapasalo et al., 2002). On the other hand, there is evidence that TrkB-T may signal independently of TrkB-FL and during development of mammalian cerebral cortex may mediate BDNF-induced differentiation of neural stem cells toward glial progenitors and astrocytes (Cheng et al., 2007). The observation that the exposure to VPA reduces the expression of TrkB-T suggests the possibility that the drug may also impair BDNF signaling through these receptors. Additional experiments in cells that predominantly express TrkB-T, such as glia cells (Rose et al., 2003), are required specifically to address this point.

A line of evidence supports the possibility that VPA downregulates TrkB through an epigenetic mechanism involving HDAC inhibition, depletion of EZH2, and upregulation of the TrkB suppressor RUNX3. Thus, like VPA different HDAC inhibitors downregulated the expression of TrkB and curtailed BDNF-induced intracellular signaling. These effects were induced not only by sodium butyrate and trichostatin A, which, like VPA, are known to inhibit multiple HDAC isoforms, but also by the class I inhibitors romidepsin and entinostat. This finding, together with the observation that the class II inhibitor MC 1568 was without effect, suggests the involvement of class I HDACs in the negative control of TrkB expression. This possibility is also supported by the observation that cell depletion of HDAC1 by siRNA treatment mimicked the inhibitory effect of VPA on TrkB expression.

HDAC1 and HDAC2 have been shown to interact with EZH2 through the EED protein, another PRC2 core component (van der Vlag and Otte, 1999; Varambally et al., 2002), and inhibition of HDAC or EZH2 activity has been shown to induce a pharmacologic disruption of the PRC2 complex likely by promoting the proteosome-mediated degradation of its core components (Varambally et al., 2002; Fiskus et al., 2006; Tan et al., 2007; Wang et al., 2012). In agreement with these data, we found that in human neuroblastoma cell lines and mouse cortical neurons, VPA and entinostat decreased EZH2 protein levels. Moreover, in differentiated SH-SY5Y cells, a reduced EZH2 expression was also found to be associated with TrkB downregulation induced by either HDAC1 knockdown or DZNep treatment.
EZH2 has been shown to participate in the epigenetic silencing of RUNX3 gene (Chuang and Ito, 2010) and in human neuroblastoma cells EZH2 depletion has been found to derepress RUNX3 expression (Wang et al., 2012). RUNX3 has been shown to suppress TrkB in differentiating sensory neurons (Kramer et al., 2006), and, when transfected in RA-treated neuroblastoma cells, to abrogate TrkB expression likely by direct binding to distal regulatory sequences in the TrkB gene (Inoue et al., 2007). Consistent with their ability to decrease EZH2 levels, VPA, entinostat, HDAC1 knockdown, and DZNep increased the cellular content of RUNX3. Moreover, silencing of RUNX3 gene prevented VPA-induced RUNX3 elevation and TrkB downregulation. The possibility that VPA downregulates TrkB by promoting the inhibition of TrkB gene expression through RUNX3 is also consistent with the finding that the drug caused a significant decrease in TrkB mRNA levels.

Whether VPA can regulate TrkB also through non-HDAC-dependent processes remains to be investigated. VPA has been shown to regulate intracellular pathways, such as the MEK/ERK and the PI3K/Akt/GSK-3β cascades, which are known to regulate gene transcription (Chiu et al., 2013). Importantly, these pathways commonly lead to activation of the transcription factor CREB, which has been shown to act as a positive regulator of the TrkB gene in neurons (Lei and Parada, 2007). Thus, the outcome of this process would likely be upregulation, rather than downregulation, of TrkB.

Prolonged exposure to IFN-β has been reported to downregulate TrkB expression and functional activity in differentiated SH-SY5Y cells and primary neurons (Dedoni et al., 2012). A rapid and marked decrease of cell surface expression of TrkB also occurs following treatment of neurons with BDNF (Sommerfeld et al., 2000). In the present study, we did not examine the effects of these TrkB downregulators under the same experimental conditions used for VPA, so that the relative efficacies of these different agents in suppressing TrkB were not determined.

The finding that VPA and other HDAC inhibitors downregulate TrkB expression and signaling may have important implications for the therapeutic use of these compounds, notably as antitumor agents. TrkB is highly expressed in neuroblastoma and in aggressive tumors of pancreas, prostate, and lymphoid tissue. In human neuroblastoma, the occurrence of BDNF/TrkB signaling is known to promote tumor survival, resistance to chemotherapy, anoikis, and metastasis (Nakagawara et al., 1994; Matsumoto et al., 1995; Midlemas et al., 1999; Douma et al., 2004). In neuroblastoma specimens, TrkB-FL expression has been found to be associated with MYCN gene amplification,
a negative prognostic marker of this tumor (Nakagawara et al., 1994). Preclinical studies have demonstrated that HDAC inhibitors possess potent anticancer activity for highly malignant tumors, such as neuroblastoma (Witt et al., 2009; West and Johnstone, 2014). The present study suggests that VPA and class I HDAC inhibitors may be particularly useful for treating aggressive tumors expressing TrkB.

In differentiated SH-SY5Y cells, the expression of TrkA was not significantly affected by VPA, whereas the protein levels of TrkC and p75NTR were markedly elevated by the drug. This indicates that VPA treatment differentially affected neurotrophin receptor expression. Interestingly, the expression of TrkC is a favorable prognostic factor in neuroblastomas (Yamashiro et al., 1996; Ryden et al., 1996) and medulloblastomas (Segal et al., 1994). Unlike TrkA and TrkB, both p75NTR and TrkC have been shown to act as dependence receptors, which in the absence of the ligand trigger apoptotic cell death (Bouzas-Rodriguez et al., 2010). Thus, their induction by VPA may constitute an additional mechanism for inhibition of the antitumor action of this drug.

We observed that VPA and entinostat downregulated TrkB expression and signaling also in mouse primary cortical neurons and altered EZH2 and RUNX3 protein levels in a manner similar to that observed in human neuroblastoma cells. These results suggest that the drugs are able to affect the epigenetic control of TrkB expression also in nontumor neuronal cells and independently of cell pretreatment with RA. The functional significance of VPA-induced TrkB downregulation in cortical neurons remains to be established. TrkB inhibition is considered a potential therapeutic target for some central nervous system-related disorders, such as epilepsy and neuropathic pain, which are effectively treated with VPA (Bouille et al., 2012). Additional studies are required to investigate whether the downregulation of TrkB contributes to the beneficial effects of VPA in these neurologic diseases.
