LD_{50}: median lethal dose

ACTH: adrenocorticotropic hormone

ANOVA: analysis of variance

CI: confidence interval

E_{max}: maximum effect

**Recommended Section:** Drug Discovery and Translational Medicine
Abstract

Etomidate is a potent and rapidly acting anesthetic with high therapeutic index (TI) and superior hemodynamic stability. However, side-effect of suppressing adrenocortical function limits its clinical use. To overcome this side-effect, we designed a novel etomidate analogue EL-0052, aiming to retain beneficial properties of etomidate and avoid its disadvantage of suppressing adrenocortical steroid synthesis. Results exhibited that EL-0052 enhanced GABA<sub>A</sub> receptors currents with a concentration for 50% of maximal effect (EC<sub>50</sub>) of 0.98 ± 0.02 μM, which was about three times more potent than etomidate (3.07 ± 1.67 μM). Similar to hypnotic potency of etomidate, EL-0052 exhibited loss of righting reflex (LORR) with ED<sub>50</sub>s of 1.02 (0.93-1.20) mg/kg in rats, and 0.5 (0.45-0.56) mg/kg in dogs. The TI of EL-0052 in rats was 28, higher than 22 of etomidate. There was no significant difference in hypnotic onset time, recovery time and walking time between EL-0052 and etomidate in rats. Both of them had minor effects on mean arterial pressure (MAP) in dogs. EL-0052 had no significant effect on adrenocortical function in dogs even at a high dose (4.3×ED<sub>50</sub>), whereas etomidate significantly inhibited corticosteroid secretion. The inhibition of cortisol synthesis assay showed that EL-0052 had a weak inhibition on cortisol biosynthesis in human H259 cells with a half inhibitory concentration (IC<sub>50</sub>) of 1050 ± 100 nM, which was 2.09 ± 0.27 nM for etomidate. EL-0052 retains the favorable properties of etomidate, including potent hypnotic effect, rapid onset and recovery, stable hemodynamics and high therapeutic index without suppression of adrenocortical function.
Significance Statement

The novel etomidate analogue EL-0052 retains the favorable properties of etomidate without suppressing adrenocortical function and provides a new strategy to optimize the structure of etomidate.
Introduction

As a potent and rapidly acting anesthetic, etomidate displays many favorable clinical properties, such as high therapeutic index and superior hemodynamic stability. However, the inhibitory effect of etomidate on adrenocortical increases the morbidity and mortality of patients, especially for those undergoing intensive care or receiving continuous infusion (Albert et al., 2011; Forman, 2011; Chan et al., 2012; Komatsu et al., 2013), which limits its clinical applications. Therefore, it is necessary to chemically modify etomidate to maintain its advantages and overcome its shortcomings.

Previous structure-activity relationship studies on etomidate have indicated that imidazole ring and ester moiety are the main groups that inhibit the biosynthesis of adrenocortical steroid (Ouellet et al., 2008; Atucha et al., 2009; Gay et al., 2009; Sneyd, 2012; Pejo et al., 2016). Currently, replacing the nitrogen atom in the imidazole ring with carbon atoms or modifying the ester group is the most commonly used strategies to reduce corticosteroid toxicity of etomidate. The corresponding chemical entities that have been successfully discovered include carboetomidate, MOC-etomidate, etc (Cotten et al., 2009; Cotten et al., 2010; Pejo et al., 2012; Campagna et al., 2014; Wang et al., 2017). These etomidate analogues can significantly reduce the activity of adrenocortical suppression, but most of them have a lower hypnotic potency than etomidate, which may increase the safety risk and bring some difficulties in formulation (Cotten et al., 2009; Cotten et al., 2010; Pejo et al., 2012; Sneyd, 2012; Campagna et al., 2014; Wang et al., 2017).
It has been reported that many imidazole-containing medications (e.g., cimetidine, ketoconazole) inhibit the specific isozymes of cytochrome P450 (CYP450) by binding to the heme iron atom and blocking oxygen binding (Seward et al., 2006; Ouellet et al., 2008). 11-β hydroxylase (CYP11B1), a member of the CYP450 superfamily, is a key enzyme for the synthesis of corticosteroids. Studies have shown that the basic nitrogen on the imidazole ring of etomidate can form a coordination bond with heme iron in the active center of 11-β hydroxylase (Roumen et al., 2007), thus inhibiting the bioactivity of 11-β hydroxylase and ultimately leading to a decrease in corticosteroid synthesis (Pejo et al., 2016). It has been showed that reducing the coordination of nitrogen with heme iron can reduce etomidate’s inhibitory effect on adrenocortical function (Cotten et al., 2010). Based on these findings, we hypothesized that replacing the hydrogen atom beside the imidazole nitrogen with a highly electronegative group could reduce the electron cloud density of nitrogen in the imidazole ring, thereby weakening the coordination of nitrogen with heme iron, and ultimately reducing etomidate’s inhibitory effect on 11-β hydroxylase. In addition, such modification might retain hypnotic effects due to the preservation of imidazole nitrogen and ester moiety. To test this hypothesis, we synthesized a series of compounds, and screened out a lead compound ethyl R-(+)-4-fluoro-1-(1-Phenylethyl)-1H- imidazole-5-carboxylate (EL-0052) (Figure 1B). Furthermore, we examined the hypnotic effect, hemodynamic stability and adrenocortical toxicity of EL-0052 in comparison with etomidate.
Materials and Methods

Materials

Etomidate and propofol were provided by Jiangsu Nhwa Pharmaceutical Corporation Ltd. (Xuzhou, China). EL-0052 was provided by Jiangsu Nhwa-Luokang Pharma R&D Ltd. (Chongqing, China). The information about synthesis and purity methods of EL-0052 were described in the patent US10392352 and the data can be freely accessed. Hypnotics were dispensed in 20% medium and long chain fat emulsion injection (No. 80KG045, Huarui pharmaceutical Company Ltd.) for in vivo tests, and dissolved in 0.5% DMSO for in vitro tests. The chemical structures of etomidate and EL-0052 were showed in Figure 1.

Animals

Wistar rats (280-330 g) were purchased from Shanghai SIPPR-BK Lab Animal Co., Ltd. Beagle dogs were purchased from Department of Laboratory Animal Science, Shanghai Jiao Tong School of Medicine. All animal experiments were conducted in accordance with Guide for Care and Use of Laboratory Animals (8th edition) and approved by Institutional Animal Care and Use Committee (IACUC) of Jiangsu Nhwa Pharmaceutical Corporation Ltd. (Xuzhou, China).

Gamma-aminobutyric Acid A (GABA\textsubscript{A}) Receptor Electrophysiology

HEK293 cells stably expressing human GABA\textsubscript{A} receptors (α\textsubscript{1}β\textsubscript{2}γ\textsubscript{2}) were provided by ICE Bioscience Co. Ltd (Beijing, China). 5×10^3 HEK293 cells were planted on a piece of cover glass and incubated in buffer solution (140 mM NaCl, 5 mM CsCl, 2 mM CaCl\textsubscript{2}, 1 mM MgCl\textsubscript{2}, 5 mM HEPES, 10 mM Glucose, pH=7.4) for
18 hours before electrophysiologic experiments. Whole cell patch clamp technique was used to record the changes in average whole cell currents. Etomidate and EL-0052 were dissolved in DMSO as stock solutions. The final working solutions contained 2 μM GABA and etomidate or EL-0052 of 0.01, 0.1, 1, 10, and 100 μM. GABA current activated by 2 μM GABA was stably recorded for 30 seconds before a cell was continuously perfused with the working solutions containing 2 μM GABA and tested drugs in increasing concentrations. The washout interval was 2 minutes. 2 μM GABA was given again to test the reversibility of GABA_A receptors after the perfusion of 100 μM drug solution. For each concentration of tested drugs, at least three independent assays were performed. The peak current amplitudes were normalized to control currents elicited by 2 μM GABA. EC_{50}s of etomidate and EL-0052 were calculated using GraphPad Prime 5.0.

**Determination of Median Effective Dose (ED_{50}) for LORR and Median Lethal Dose (LD_{50})**

The Dixon’s up-and-down sequential allocation method was used to determine the ED_{50} for LORR and LD_{50} of EL-0052, etomidate or propofol (Dixon, 1991).

The ED_{50} test for LORR was performed in male rats and male dogs. We first conducted a preliminary test to find out the approximate dose range of ED_{50} and LD_{50}, then set a series of doses with an interval of 1.25 times between each dose group for the formal test. In the formal test, the desired doses of EL-0052 (0.82, 1.02 and 1.28 mg/kg for rats, and 0.45, 0.56 and 0.7 mg/kg for dogs), etomidate (0.66, 0.82 and 1.02 mg/kg for rats, and 0.30, 0.38, 0.47 and 0.59 mg/kg for dogs), and
propofol (4, 5 and 6.25 mg/kg for rats, and 1.94, 2.43 and 3.04 mg/kg for dogs) were injected intravenously within 10 s (rats) or 30 s (dogs) followed by a normal saline flush. The volume of saline flush was 1 mL and it was injected within 10 s. After injection, animals were placed with their back on a table (for rats) or lay on their sides (for dogs). An animal was judged to have LORR if losing its ability to right itself (onto all four paws) immediately.

In the LD$_{50}$ test, male rats were injected intravenously with a series of doses of EL-0052 (25.6, 32 and 40 mg/kg) or etomidate (16.4, and 20.5 mg/kg) through tail vein within 10 s. The death rate of rats was observed in 30 minutes after injection.

**Duration of LORR in Rats**

Male Wistar rats weighing 280-330 g were first placed in plastic restrainers before intravenously injection with 20% medium and long chain fat emulsion injection (as a negative control), EL-0052 (2.04 mg/kg) or etomidate (1.64 mg/kg) at 2$\times$ED$_{50}$ doses and the duration of injection was 10 s. Animals were removed from restraint devices immediately after injection and turned gently on their backs to assess the duration of LORR. A stopwatch was used to record the time from the injection to recovery. The onset time was defined as the time from injection to LORR. The recovery time was defined as the time when animals regained the ability to right themselves after LORR. The walking time was defined as the time when any hind limb of animals took the first step after the recovery of righting reflex.

In order to avoid subjective differences, all behavioral experiments (ED$_{50}$, LD$_{50}$ and LORR tests) were conducted blindly. Behavioral observations and recording
were performed by a specially trained individual who was blinded to different treatments.

**Mean Arterial Pressure (MAP) Measurement in Beagle Dogs**

24 beagle dogs with stable blood pressure were screened out by non-invasive blood pressure monitor (BP-2010E, Softron, Japan), and randomly divided into 6 groups: vehicle, propofol (6 mg/kg, 2.5×ED$_{50}$), etomidate (1.15 mg/kg, 2.5×ED$_{50}$), etomidate (2 mg/kg, 4.3×ED$_{50}$), EL-0052 (1.26 mg/kg, 2.5×ED$_{50}$) and EL-0052(2.17 mg/kg, 4.3×ED$_{50}$) group, with 2 male dogs and 2 female dogs in each group. The doses of propofol (6 mg/kg) and etomidate (2 mg/kg) were set according to that of Campagna (Campagna et al., 2014). MAP was measured by a tail-cuff method using non-invasive blood pressure monitor in conscious dogs. Each dog with a tail cuff was placed in casting harness and allowed to acclimate for at least 10 minutes. The desired doses of anesthetic agents or vehicle (20% medium and long chain fat emulsion injection, as a negative control) were injected via the forelimb cephalic vein in 30 seconds. The blood pressure was recorded every 1 minute for 5 minutes prior to drug administration and every 1 minute for 20 minutes thereafter. The MAP at each time point after drug administration was compared with the baseline (mean of MAP recorded 5 minutes before drug administration).

**Suppression of Cortisol Synthesis in H259R Cells**

The *in vitro* effect of EL-0052 on the cortisol synthesis was investigated using human adrenocortical cell line H259R (NCI-H295R, Cell Culture center, Chinese Academy of Medical Science). H259R cells were suspended in growth medium
(DMEM/F12 supplement with 1% insulin-transferrin-selenium, 1.25 mg/mL BSA, 2.5% FBS, 15 mM HEPES, and 0.0053 mg/mL linoleic acid) and the cell density was adjusted to $10^5$ cells/mL. The cell suspension was seeded in a 12-well plate with 2 mL in each well, and cultured at 37 °C under 5% CO₂. The growth medium was replaced with maintenance medium (DMEM/F12 supplement with 1% insulin-transferrin-selenium and 20 µM Forskolin) when cell density reached about 80%. Each well was added with 1.98 mL of maintenance medium and 0.02 mL of etomidate (final concentrations: 0.032, 0.16, 0.8, 4, 20 and 100 nM) or EL-0052 (final concentrations: 3.2, 16, 80, 400, 2000 and 10000 nM) with triple duplication for each concentration. After incubation at 37 °C under 5% CO₂ for 48 h, 1.2 mL maintenance medium were collected and centrifuged at 1000 rpm for 5 minutes. The concentrations of cortisol in the supernatant were determined by ELISA kits (R&D SYSTEMS, USA). IC₅₀ was calculated using GraphPad Prime 5.

**Adrenocortical Suppression Test in Dogs**

Suppression of adrenocortical synthesis in dogs was performed as previously reported (Cotten et al., 2010). Briefly, 18 beagle dogs were randomly divided into vehicle, etomidate (2 mg/kg, 4.3×ED₅₀), and EL-0052 (2.17 mg/kg, 4.3×ED₅₀) groups with 3 male and 3 female dogs in each group. Dexamethasone (0.1 mg/kg) was intravenously administered to each dog to suppress corticosterone production. 4 mL blood was sampled two hours later. Then vehicle (20% medium and long chain fat emulsion injection, as a negative control) or tested drug along with adrenocorticotropic hormone (ACTH₁⁻₂₄) (20 µg/kg, Sigma) was injected
successively to stimulate corticosterone production. Another 4 mL blood was collected 15 minutes after ACTH injection. The concentrations of cortisol and corticosterone were quantified by ELISA kits (R&D SYSTEMS, USA).

**Statistical Analysis**

All data were expressed as the mean ± SEM unless otherwise noted. The EC$_{50}$s for GABA$_A$ receptor function assay and the IC$_{50}$s for the H259R cell cortisol suppression assay were calculated using nonlinear regression analysis in GraphPad Prism 5, according to the following equation: $Y = \text{Bottom} + \frac{(\text{Top}-\text{Bottom})}{(1+10^{(\text{LogEC}_{50}-X) \times \text{Hillslope}}))$. Results were reported as EC$_{50}$s or IC$_{50}$s and SEM. The ED$_{50}$s for LORR test and LD$_{50}$s for acute toxicity test were determined using the up-and-down procedure according to the OECD/OCDE test guidelines on acute oral toxicity under a computer-guided statistical programme-AOT425statPgm, version 1.0 (AOT, 2001). Results were expressed as ED$_{50}$s or LD$_{50}$s with 95% confidence intervals (95%CI).

Data for behavioral and physiological were compared using one-way or two-way analysis of variance (ANOVA) followed by a Tukey multiple comparison test. Data for serum corticosterone concentrations or MAP values were analyzed using two-way repeated measures ANOVA, followed by a Bonferroni post-test. The statistical analysis was performed with SPSS 19.0. The value of $P < 0.05$ was considered to be statistically significant.

**Results**

**Activation of GABA$_A$ receptors currents by EL-0052**
It has been reported that etomidate exerts hypnotic effects by modulating GABA_A receptors (Belelli et al., 2003). To test whether EL-0052 modulating GABA_A receptors, the effects of EL-0052 on human α₁β₂γ₂ GABA_A receptors were evaluated. Both EL-0052 and etomidate enhanced the currents of GABA_A receptors activated by 2 μM GABA in a concentration-dependent manner, and their EC_{50}s were 0.98 ± 0.02 μM and 3.07 ± 1.67 μM, respectively (Figure 2A-2C). The results indicated that EL-0052 was 3 times more potent than etomidate. However, the maximum effect (Emax) of EL-0052 on enhancing the currents elicited by 2 μM GABA was about half that of etomidate.

**Hypnotic properties of EL-0052 in Rats and Dogs**

In order to reduce etomidate-induced corticosteroid suppression, a series of etomidate analogues were developed, but most of them reported compromise hypnotic properties (Cotten et al., 2009; Cotten et al., 2010; Ge et al., 2012; Pejo et al., 2012; Sneyd, 2012; Ge et al., 2014; Wang et al., 2017). Therefore, tests were conducted to clarify whether EL-0052 could retain the hypnotic properties of etomidate in rats and dogs. The ED_{50}s of EL-0052, etomidate and propofol in rats were 1.02 mg/kg (95%CI: 0.93-1.20 mg/kg), 0.82 mg/kg (95%CI: 0.68-0.88 mg/kg) and 5.12 mg/kg (95%CI: 4.40-5.71 mg/kg), respectively (Table 1, Figure 3A and 3B). The ED_{50}s of EL-0052, etomidate and propofol in dogs were 0.50 mg/kg (95%CI: 0.45-0.56 mg/kg), 0.46 mg/kg (95%CI: 0.27-0.58 mg/kg) and 2.43 mg/kg (95%CI: 1.94-3.1 mg/kg), respectively (Table 1, Figure 3A and 3B). The hypnotic potency of EL-0052 was similar to that of etomidate in rats and dogs. The dose of 2×ED_{50} was...
sufficient to produce LORR in rats, and there was no significant difference between EL-0052 and etomidate in hypnotic onset time \( (P = 0.558) \), recovery time \( (P = 0.082) \) and walking time \( (P = 0.801) \) (Figure 4A and 4B). These results demonstrated that EL-0052 retained etomidate’s favorable hypnotic properties of rapid onset and fast recovery after a single dose administration.

In order to calculate the TI, we further performed the acute toxicity test to obtain the \( \text{LD}_{50} \) value of EL-0052 and etomidate in rats. The \( \text{LD}_{50}s \) of EL-0052 and etomidate in rats were 29 mg/kg (95%CI: 26-32 mg/kg) and 18 mg/kg (95%CI: 16-21 mg/kg), respectively. Accordingly, the TI of EL-0052 was 28, higher than 22 of etomidate (Table 1).

**Hemodynamic Actions of EL-0052 in Beagle Dogs**

In clinical applications, one of the superior properties of etomidate over propofol is hemodynamic stability. To determine whether EL-0052 maintained the excellent properties of etomidate, the effects of EL-0052, etomidate and propofol on hemodynamics were compared in Beagle dogs. Propofol significantly reduced MAP in dogs. Etomidate and EL-0052 also produced a brief reduction in MAP, but there was no significant difference compared with the baseline (Figure 5A and 5B). At the dose of \( 2.5 \times \text{ED}_{50} \), the maximum inhibition rates of propofol, etomidate and EL-0052 on MAP were 30%, 17% and 16%, respectively, indicating that the inhibitory effects of etomidate and EL-0052 on MAP was weaker than that of propofol at equivalent doses. At the high dose of \( 4.3 \times \text{ED}_{50} \), the maximum inhibition rates of etomidate and EL-0052 on MAP were 21% and 22%, respectively, which
was similar to that of propofol at the dose of $2.5 \times \text{ED}_{50}$, but the duration of blood pressure inhibition of these two drugs were shorter than propofol.

**Comparison of Adrenocortical Suppression between EL-0052 and etomidate both in cells and dogs**

EL-0052 was designed to be of no inhibition of corticosteroids. To verify whether EL-0052 had any effects on corticosteroid suppression, the inhibitory effects of EL-0052 and etomidate on cortisol biosynthesis in human H259R cells were examined. The IC$_{50}$ of EL-0052 inhibiting cortisol was $1050 \pm 100$ nM, which was about 500-fold less potent than etomidate ($2.09 \pm 0.27$ nM) (Figure 6A). In dog adrenocortical suppression test, the baseline levels of serum cortisol and corticosterone concentrations were similar among the groups of vehicle ($6.06 \pm 1.13$ ng/mL & $7.56 \pm 1.40$ ng/mL), etomidate ($7.30 \pm 1.16$ ng/mL & $10.45 \pm 1.69$ ng/mL) and EL-0052 ($8.46 \pm 1.71$ ng/mL & $5.51 \pm 0.72$ ng/mL) under dexamethasone inhibition (Figure 6B and 6C). Fifteen minutes after ACTH$_{1-24}$ injection, the serum cortisol and corticosterone levels were $17 \pm 3.04$ ng/mL and $28.04 \pm 4.59$ ng/mL in the vehicle group, $8.54 \pm 2.38$ ng/mL and $6.13 \pm 0.56$ ng/mL in the etomidate group, and $15.99 \pm 2.40$ ng/mL and $30.95 \pm 2.12$ ng/mL in the EL-0052 group (Figure 6B and 6C). Compared with the vehicle group, etomidate significantly inhibited ACTH-induced increase of corticosteroids ($P = 0.021$ for cortisol and $P = 0.001$ for corticosterone). In contrast, EL-0052 had no significant effect on ACTH$_{1-24}$ induced corticosteroid elevation ($P = 0.817$ for cortisol and $P = 0.611$ for corticosterone) (Figure 6B and 6C), indicating that EL-0052 had no effect.
on adrenocortical suppression in dogs after a single dose administration.
Discussion

In this study, we describe the pharmacological properties of EL-0052, an etomidate analogue, in which a hydrogen atom in the 4th position of imidazole ring of etomidate is replaced with a fluorine atom. We find that EL-0052 potently enhances GABA_A receptor’s function, displays excellent hypnotic properties with high hypnotic potency, rapid onset and fast recovery, and maintains hemodynamics stability. Most importantly, EL-0052 has no significant effect on corticosteroid secretion in dogs even at very high doses.

The adrenal function suppression is a major side effect of etomidate, which limits its clinical applications (Annane, 2005). It has been identified that the inhibition of 11-β hydroxylase is the main cause of etomidate induced adrenocortical suppression. The basic imidazole nitrogen is also considered to be responsible for the binding of etomidate and 11-β hydroxylase (Roumen et al., 2007). To reduce the adrenocortical toxicity of etomidate, our strategy is to replace the hydrogen atom with a highly electronegative fluorine atom on 4th position of imidazole ring of etomidate. Selective replacement of the hydrogen atom with a fluorine atom is a strategy widely used in bio-organic and medicinal chemistry (Richardson, 2016). The high electronegativity of the fluorine can have significant electronic effect on the properties of organic compounds (Yerien et al., 2016). Theoretically, after introducing a fluorine atom into the imidazole ring of etomidate, the electron cloud density of the nitrogen atom on the imidazole ring of EL-0052 will be greatly reduced, and the coordination effect with heme iron will be correspondingly reduced,
thus reducing the suppression of adrenocortical function. Our study on human H259R cells demonstrates that the inhibitory potency of EL-0052 on corticosteroid synthesis is only 1/500 compared to etomidate. The assays in dogs further confirm that the adrenocortical suppression of EL-0052 is remarkably lower than that of etomidate, as EL-0052 has no significant effect on adrenocortical function ($P = 0.817$ for cortisol and $P = 0.611$ for corticosterone), while etomidate significantly inhibits corticosteroids secretion ($P = 0.021$ for cortisol and $P = 0.001$ for corticosterone). These results indicate that EL-0052 avoids the corticosteroid inhibitory effects that are common for etomidate. Therefore, EL-0052 has potential for clinical use as a maintenance anesthetic.

Maintaining stable cardiovascular function is a key factor for guaranteeing success of surgery. Our study finds that EL-0052 and etomidate exhibit no significantly impact on MAP in dogs even at a very high dose ($4.3 \times \text{ED}_{50}$). In contrast, propofol markedly lowered blood pressure at the hypnotic dose ($2.5 \times \text{ED}_{50}$). This finding suggests that EL-0052 may have a significant advantage over propofol in maintaining cardiovascular stability in clinical applications.

Although currently reported etomidate analogues can reduce the inhibitory effect of corticosteroids and maintaining cardiovascular stability, such as carboetomidate, MOC-etomidate and MOC-carboetomidate, their hypnotic potency is greatly reduced. The $\text{ED}_{50}$s of carboetomidate, MOC-etomidate, MOC-carboetomidate and ET26 in rats are 7.2 mg/kg, 5.2 mg/kg, 13.5 mg/kg and 2.35 mg/kg, respectively, which are much lower than that of etomidate (1 mg/kg).
(Cotten et al., 2009; Cotten et al., 2010; Pejo et al., 2012; Sneyd, 2012; Wang et al., 2017). In contrast, our results show that EL-0052 not only maintains cardiovascular stability and eliminates adrenocortical inhibition, but also retains the potent hypnotic efficacy and excellent hypnotic properties of etomidate, indicating that the imidazole nitrogen and the ester moiety are vital for inhibiting the synthesis of corticosteroids and for producing the anesthesia effect. The ED$_{50}$s of EL-0052 in rats and dogs are 1.02 mg/kg (95%CI: 0.93-1.20 mg/kg) and 0.50 mg/kg (95%CI: 0.45-0.56 mg/kg), respectively, which is similar to that of etomidate with ED$_{50}$s of 0.82 mg/kg (95%CI: 0.68-0.88 mg/kg) and 0.46 mg/kg (95%CI: 0.27-0.58 mg/kg). At the hypnotic doses, there are no significant difference in hypnotic onset time ($P = 0.558$), recovery time ($P = 0.082$) and walking time ($P = 0.801$) between EL-0052 and etomidate in rats LORR tests, indicating that EL-0052 retains the favorable hypnotic properties of etomidate with rapid onset and fast recovery after a single dose administration.

In addition to the aforementioned properties, we also find that EL-0052 has a TI of 28, which is higher than etomidate (22) and propofol (3.4) (Forman, 2011), suggesting that EL-0052 may be safer than etomidate and propofol in clinical applications.

There are some limitations in our study. We only evaluated the hypnotic effect of EL-0052 in a single administration, but did not conduct the hypnotic tests under continuous infusion. In addition, the pharmacokinetic properties of EL-0052 were not explored. And we will carry out these experiments to evaluate more properties of EL-0052 in further research.
In summary, EL-0052 not only retains the favorable properties of etomidate including potent hypnotic effect, rapid onset and recovery, stable hemodynamics and high therapeutic index, but also avoids adrenocortical function suppression. Our findings demonstrate a feasibility to modify etomidate by replacing hydrogen atoms beside the imidazole nitrogen with other substitution groups for reduction of adrenocortical toxicity while maintaining the hypnotic effect.
Authorship Contributions

Participated in research design: Xiangqing Xu, Wengao Jiang, Qingeng Li

Conducted Experiments: Xiangqing Xu, Yingying Dong, Yinli Qiu, Zhanbiao Mei, Kai Wang, Jingya Xiu, Tao Wang, Lingguo Zeng, Xiaohu Dong, Yi Shen

Performed data analysis: Xiangqing Xu, Qingeng Li

Wrote or contributed to the writing of the manuscript: Xiangqing Xu, Yaqin Wei, Wengao Jiang, Qingeng Li

Declarations of Interest

Jiangsu Nhwa-Luokang Pharma R&D Ltd. has submitted patent applications for EL-0052 and related analogues. This study was supported by Jiangsu Nhwa-Luokang Pharma R&D Ltd. and Jiangsu Nhwa Pharmaceutical Co., Ltd., which played a role in study design, data collection and analysis, decision to publish and preparation of the manuscript. Kai Wang, Jingya Xiu, Tao Wang and Qingeng Li are research staff of Jiangsu Nhwa-Luokang Pharma R&D Ltd.. Xiangqing Xu, Yingying Dong, Yinli Qiu and Zhanbiao Mei are research staff of Jiangsu Nhwa Pharmaceutical Co., Ltd.. This does not alter the authors’ adherence to all the policies of The Journal of Pharmacology and Experimental Therapeutics on sharing data and materials. Yaqin Wei and Wengao Jiang have no conflicts of interest to declare.
References

analog of etomidate designed not to suppress adrenocortical function.

Anesthesiology 112:637-644.

Komatsu R, You J, Mascha EJ, Sessler DI, Kasuya Y and Turan A (2013) Anesthetic induction with etomidate, rather than propofol, is associated with increased
30-day mortality and cardiovascular morbidity after noncardiac surgery. 

Footnotes

The work was supported by the National Natural Science Foundation of China (Grant No. 31600827). We thank Jiangsu Nhwa-Luokang Pharma R&D Ltd. and Jiangsu Nhwa Pharmaceutical Co., Ltd. in study design, data collection and analysis.
**Figure Legends**

**Figure 1.** Chemical structure of etomidate (A) and EL-0052 (B).

**Figure 2.** Enhancement effects of EL-0052 and etomidate on human gamma-aminobutyric acid A (GABA_A) receptor current. (A) Representative traces showing enhancement of currents activated by 2 μM GABA by different concentrations of etomidate and EL-0052. Direct activation of GABA_A receptors by etomidate (B) and EL-0052 (C). Current amplitudes were normalized to that activated by 2 μM GABA. The data of curves were fitted to Hill equation yielding an EC_{50}s of 3.07 ± 1.67 μM for etomidate and 0.98 ± 0.02 μM for EL-0052, respectively. Each data point represents the mean ± SEM from three independent experiments.

**Figure 3.** EL-0052 and etomidate dose-response curves for loss of righting reflex (LORR) in rats (A) and dogs (B). Each data point represents the results from a single animal. The ED_{50}s were determined using the up-and-down procedure according to OECD/OCDE test guidelines on acute oral toxicity under a computer-guided statistical programme-AOT425statPgm, version 1.0 (AOT, 2001). The ED_{50} of EL-0052 and etomidate in rats were 1.02 mg/kg (95%CI: 0.93-1.20 mg/kg) and 0.82 mg/kg (95%CI: 0.68-0.88 mg/kg), respectively. The ED_{50} of EL-0052 and etomidate in dogs were 0.50 mg/kg (95%CI: 0.45-0.56 mg/kg) and 0.46 mg/kg (95%CI: 0.27-0.58 mg/kg), respectively.
**Figure 4.** The onset time (A), recovery time and walking time (B) observed after intravenous administration of 2×ED$_{50}$ EL-0052 or etomidate in rats (n=10). The doses of EL-0052 and etomidate were 2.04 mg/kg and 1.64 mg/kg, respectively. Under this equivalent dose, there was no significant difference in hypnotic efficacy between the two groups.

**Figure 5.** Effects of etomidate, propofol and EL-0052 on mean arterial pressure (MAP) in Beagle dogs. (A) Effects of a bolus injection of 2.5×ED$_{50}$ etomidate, propofol and EL-0052 on MAP in dogs (n = 4). (B) Effects of a bolus injection of 4.3×ED$_{50}$ etomidate and EL-0052 on MAP in dogs (n = 4). The doses of propofol (6 mg/kg, 2.5×ED$_{50}$) and etomidate (2 mg/kg, 4.3×ED$_{50}$) were determined according to that of Campagna.(Campagna et al., 2014) Each data point represents the mean ± SEM of MAP recorded every 1 minute using non-invasive blood pressure monitor. * $p<0.05$, ** $p<0.01$ versus the baseline (mean of MAP recorded 5 minutes before drug administration).

**Figure 6.** The effects of etomidate and EL-0052 on adrenocortical function in *vitro* and *in vivo*. (A) The effects of etomidate and EL-0052 on biosynthesis of cortisol in human adrenocortical tumor cell line H259R. The data of curves are fitted to Hill equation. The IC$_{50}$ was 1050 ± 100 nM and 2.09 ± 0.27 nM for EL-0052 and etomidate, respectively. Each data point represents the mean ± SEM from three
independent experiments. The results from dog adrenocortical suppression tests showed that 4.3×ED$_{50}$ of EL-0052 (at 2.17 mg/kg) didn’t decrease the concentrations of cortisol (B) and corticosterone (C) in dog plasma 15 minutes after adrenocorticotropic hormone stimulation. Six dogs were studied in each group. *, $P < 0.05$, **, $P < 0.01$. N.S.: no significant difference.
